Influence of the agricultural associations and corporations on the organization of the German labor market (*Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intl., 3 (1912), No. 3, pp. 36-47*).—The progress in industrial centers, depopulation of rural districts, new methods applied in farming, and unwillingness of agricultural laborers to contract for long periods have greatly increased the demand of German farmers for foreign labor, especially for the sowing and harvesting periods. Private labor bureaus being inadequate to supply this demand, several unions and corporations have endeavored to centralize the organization of the agricultural labor market, under the Central German Agricultural Labor Bureau.

The government has recognized this bureau and bestowed upon it certain special powers with regard to the registration of foreign laborers, and in reorganizing the agricultural labor market. In 1909, the bureau procured 70,397 foreign laborers, 76,001 in 1910, and 78,296 in 1911. It legitimized, that is, authorized to remain in the German Empire, 374,751 agricultural laborers in 1910, and 387,902 in 1911. "It has begun to exert a very useful action as arbiter between foreign laborers and German masters for the benefit and to the advantage of both parties." In 1909, 280 workmen and 212 masters appealed to it to settle their differences; in 1910 there were, respectively, 523 and 220 cases, and only 47 could not be amicably adjusted.

Other data as to the work of the bureau are given.

Increasing the efficiency of farm labor, W. M. KELLY (*Mich. Farmer, 138 (1912), No. 22, p. 613, fig. 1*).—Observations are made showing that in order to secure the greatest possible efficiency of farm labor the work must be

planned in such a way as to keep the laborers busy every day. Some suggestions are made regarding selection of crops and crop rotations and the selection of live stock and farm machinery with this end in view.

**Agricultural population and its growth, A. C. LECOCO** (*Rev. Agron. [Portugal]*, 9 (1911), No. 1-6, pp. 17-44).—Notes and tables are given showing the movement of the agricultural population for a number of years in Portugal. It is noted that the rural population was 71.5 per cent of the total population in 1864, and 67.1 per cent in 1900. In 1890 the agricultural population was 3,088,610, and in 1900, 3,267,199, an increase of 9 per cent; while the non-agricultural population was 1,961,119 in 1890, and 2,055,933 in 1900, an increase of 4.8 per cent.

**Abstract of statistics of the number and distribution of inhabitants** (*Bur. of the Census [U. S.] Bul. 13*, pp. 55, figs. 6).—This bulletin presents in condensed form the principal results of the population census of 1910, including among other data tables and maps showing by divisions and States the urban and rural population in 1910, 1900, and 1890, and the increase in population during the same period.

[**Agricultural and pastoral statistics for 1910 in Queensland**], T. WEEDON (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1910-11, pp. 115-172).—Despite favorable climatic conditions for a number of years, only a small increase of cattle and sheep in Queensland is reported, this being attributed largely to the greater demand for dressed meat and meat products. Owing to governmental supervision of dairy products much recent progress is noted in dairying, the number of dairy cattle having increased from 304,281 in 1908 to 365,444 in 1910, and the quantity of butter from 17,538,473 lbs. in 1904 to 31,258,333 lbs. in 1910.

A continuous decrease in the excess of exports over imports of agricultural products from 1906 to 1910 is noted. Tables showing acreage, yield, total production, value, etc., of all crops are given. The estimated value of crops for 1910 was £3,863,707, an increase of £378,291, the principal items being sugar cane, £1,262,213; corn, £669,046; green forage, £448,335; fruits, £363,018; alfalfa hay, £322,359; wheat, £204,475; and potatoes, £132,872. A tendency is noted on the part of farmers to bring an increasing area of their holdings under cultivation, the average size of cultivated farms being 36 acres in 1908 and 40 acres in 1910.

**Rural economy in the Bombay Dekkan, G. F. KEATINGE** (*Agr. Jour. India*, 6 (1911), Nos. 3, pp. 208-220; 4, pp. 344-352).—This article discusses the general conditions under which live stock is bred and reared in Dekkan, showing that in 1910 the number of horses and ponies totaled 71,000; sheep, 1,300,000; goats, 1,200,000; buffaloes, 500,000; and cattle, 2,900,000. Of the total number of cattle, 1,315,000 are used as plow cattle, cultivating about 13,635,000 acres, horses being of little importance. The supply of work cattle is said to be 31 per cent short of the demand, due possibly to the lack of attention given toward increasing the number or improving the quality. In many localities the cows and young stock are not fed but turned out all the year to feed upon the public grazing lands, and as these are practically barren wastes from March to July, the losses are very large.

The economic significance of farm machinery in connection with the land, the farmer, and the resources of the country is discussed, also the importance of circulating and reserve capital (*E. S. R.*, 25, p. 595).

**Crop Reporter** (*U. S. Dept. Agr., Bur. Statis. Crop Reporter*, 14 (1912), No. 6, pp. 41-48, fig. 1).—Notes and statistics showing cotton condition May 25, and other crop conditions June 1, 1912, with comparisons; farm value of important products on dates indicated; foreign crop conditions; monthly receipts and stocks of eggs and poultry in the United States; range of prices of agri-

cultural products at important markets; temperature and precipitation statistics; the production of fruit and nuts in continental United States; and the causes and extent of crop damage in 1912 by States are here presented.

History of the Minnesota State Agricultural Society from its organization in 1854 to the annual meeting of 1910, D. S. HALL and R. I. HOLCOMBE (*St. Paul, Minn., 1910, pp. 405+XXIII, figs. 140*).

### AGRICULTURAL EDUCATION.

The interrelationship of agricultural colleges and experiment stations, B. YOUNGBLOOD (*College Station, Tex., 1912, pp. 15*).—This paper, presented at the Conference for the Advancement of Agriculture of the Agricultural and Mechanical College at College Station, Tex., on April 29, 1912, comments briefly "upon the history and development of the agricultural colleges of this country with a view to understanding the scope and functions of their various divisions" as a working basis upon which to develop satisfactory relationships within these institutions.

Agricultural education in secondary schools (*U. S. Bur. Ed. Bul., 1912, No. 6, pp. 53*).—This bulletin is made up of the following papers read and discussed at the annual meeting of the American Association for the Advancement of Agricultural Teaching, Columbus, Ohio, November 14, 1911: Essentials in a State System of Agricultural Education, by F. W. Howe; The Need for Reliable Scientific Data Regarding Social and Economic Conditions in the Rural Communities, by E. C. Higbie; The Proper Equipment of an Agricultural High School, by D. O. Barto and D. J. Crosby; The Smith's Agricultural School and Agricultural Education in Massachusetts, by R. W. Stimson; The Unprepared Teacher of Agriculture in High Schools and Colleges, by A. V. Storm; and What is Being Done to Prepare Teachers of Secondary School Agriculture, by A. C. Monahan. A list of other recent publications of the Bureau of Education on agricultural education is also given.

The proper equipment of an agricultural high school, D. O. BARTO and D. J. CROSBY (*U. S. Bur. Ed. Bul., 1912, No. 6, pp. 20-27*).—For the proper study of soils suitable provisions for collecting, drying, and determining their essential constituents are necessary. A laboratory should be well stocked with carefully selected, prepared, and labelled specimens of farm crops, weeds, seeds, etc. Samples of various commercial fertilizers on the market should be kept labelled to show their chemical composition. There should be a glass house properly heated, where plants may be grown and studied during the winter. Too much land should be avoided as small plats worked with care and accuracy are deemed of much more educational value than larger areas where part of the work is done by some one not connected with the school. Arrangements should be provided for pruning, budding, grafting, spraying, etc. A milk tester, separator, and churn should be provided for instruction in dairying, and the classes should visit the farms of the vicinity to study typical animals, birds, flocks, and up-to-date equipment.

The unprepared teacher of agriculture in high schools and colleges of education, A. V. STORM (*U. S. Bur. Ed. Bul., 1912, No. 6, pp. 33-40*).—The author believes that the standard of preparation for a teacher of agriculture should contain the same elements whether he is to teach agriculture in a country school, high school, normal school, or college, and would differ only in the proportionate amount of each and the special adaptation to the particular kind of school. The proper preparation for one who is to teach agriculture in a high school would be, besides moral and natural fitness, a general education consisting of actual experience on the farm, elementary training in reading, arith-

metic, language, spelling, geography, etc., and a strong high school course of 4 years distributed about as follows: Mathematics, 2½ years; English, 3 years; history and civics, 2 years; science, 3½ years; foreign language, 2 years; and electives, 3 years. If the pupil is preparing to teach in the elementary schools his advanced work could be taken at a normal school, but if in schools above those of elementary grade his advanced training should be received at a college or university. His advanced preparation should be in 4 different lines: (1) General, which includes such subjects as English, public speaking, and economics; (2) technical, constituting botany, chemistry, zoology, physiography, physics, and agriculture as a specialty; (3) professional, comprising such subjects as psychology, history of education, principles of education, principles of general method and the method of the recitation, special methods of high school subjects, and school management; and (4) practice in teaching.

It is suggested that normal schools and agricultural colleges when recommending teachers for agricultural high schools should select their candidates in the following order: (1) Those with natural ability, farm experience, and agricultural preparation, even though they have had no professional preparation or teaching experience; (2) those with natural ability, agricultural preparation, professional preparation, and teaching experience; (3) those with natural ability, farm experience, good science preparation, and teaching experience; and (4) those with natural ability, farm experience, good science preparation, and no teaching experience.

**High school agriculture subjects accepted for matriculation at the University of California** (*Col. Agr. Univ. Cal. Spec. Circ., 1912, May, pp. 4*).—This is a full outline of courses in general agriculture, animal husbandry, dairying, horticulture, farm mechanics, and farm management which may be offered by high schools in the State for entrance credits at the college of agriculture of the University of California for a total of 9 units.

**University Farm School, Davis, Cal.** (*California Sta. Circ. 77, pp. 23, figs. 13*).—This circular contains an announcement of the 3-year course of study at the institution, and briefly describes the work of the school.

**Seed testing, W. L. OSWALD** (*Univ. Minn., Dept. Agr., Ext. Bul. 24, 1911, pp. 8, figs. 12*).—Directions are given for home purity and germination seed tests.

**Oklahoma school hotbeds, S. A. MINEAR** (*Bul. Okla. Agr. and Mech. Col., 8, (1911), No. 14, pp. 7, figs. 5*).—This bulletin is intended to assist Oklahoma teachers in the construction and use of hotbeds in their schools.

**Transplanting, V. H. DAVIS** (*Agr. Col. Ext. Bul. [Ohio State Univ.], 7 (1912), No. 8, pp. 16, figs. 14*).—The author discusses transplanting operations, particularly the replacing of the lifted plant in the soil by the ultimate purchaser. Trees, shrubs, and herbaceous plants are considered separately. A homemade corn tester is described and illustrated.

**A method of illustrating the trees, J. E. KIRKWOOD** (*Nature-Study Rev., 8 (1912), No. 1, pp. 39-41, fig. 1*).—The author describes a set of botanical preparations, originally designed for the exhibit of the University of Montana at the state fair but since found of much practical value in school work. Each preparation illustrates one species and consists of a wall frame 26½ by 32½ in., containing a card on which is mounted under glass a full-sized herbarium specimen of the species, showing leaves and flowers, the fruit where practicable, a seedling, a map showing distribution, a section of the wood, several photographs of individual trees showing the character of the bark or other features, and landscape scenes depicting the habitat of the species. Some of this material may be contributed by the pupils as a part of their laboratory or field work.

A guide for the study of animals, W. WHITNEY ET AL. (*Boston, New York, and Chicago, 1911, pp. IX+197*).—This guide is intended for pupils in secondary schools, and gives particular attention to the chordates. Special prominence is given to the economic side of zoology, especially its bearing on medicine, sanitation, household science, and agriculture.

Oregon boys and girls and the egg problem, J. DRYDEN (*Oreg. Agr. Col. Bul., Ext. Ser. 2, 1912, No. 2, pp. 4*).—This bulletin gives instructions for boys and girls on feeding and housing fowls, with an estimate of the profits.

Ravenel's road primer for children, S. W. RAVENEL (*Chicago, 1912, pp. 159, pls. 21, figs. 34*).—This primer was compiled and prepared at the request of the National Congress of Mothers. It gives instruction and suggestions concerning elementary principles and practices of road making, causes and effect of good roads, their location, grades, drainage, maps and profiles, construction, and maintenance, narrow and wide tires, some kinds of roads, and machinery necessary for the use of road builders.

### MISCELLANEOUS.

Biennial Report of Connecticut Storrs Station, 1910-11 (*Connecticut Storrs Sta. Rpt. 1910-11, pp. XL+601, pls. 10, figs. 216*).—This contains the organization list, a financial statement for the fiscal years ended June 30, 1910, and June 30, 1911, reports of the director and heads of departments, reprints of Bulletins 59-69, and a general weather review, abstracted on page 414 of this issue.

Nineteenth Annual Report of Minnesota Station, 1911 (*Minnesota Sta. Rpt. 1911, pp. XLIV+188+XI, pl. 1, figs. 38*).—This contains the organization list, a list of the publications of the year, a financial statement for the fiscal year ended June 30, 1911, a report of the director summarizing the work of the station and its substations, and reprints of Bulletins 121-124, previously noted.

Twenty-second Annual Report of New Mexico Station, 1911 (*New Mexico Sta. Rpt. 1911, pp. 57, figs. 4*).—This contains the organization list, a report of the director briefly summarizing the work of the station since its establishment, lists of the changes in staff, publications, and exchanges of the year, departmental reports on the various lines of station activities during the year, and a financial statement for the fiscal year ended June 30, 1911. The report of the meteorologist and a portion of that of the horticulturist are abstracted elsewhere in this issue.

Finances, meteorology, index (*Maine Sta. Bul. 197, pp. 329-340+XII*).—This contains the organization list of the station; meteorological observations noted on page 414 of this issue; a financial statement for the fiscal year ended June 30, 1911; an index to Bulletins 187-197, which collectively constitute the twenty-seventh annual report of the station; a list of the publications issued during the year; and announcements and notes on the work, personnel, and equipment of the station.

Report of work at the Delta Branch Experiment Station for 1911, G. B. WALKER (*Mississippi Sta. Bul. 157, pp. 23, figs. 5*).—This contains a report of the work at this substation during 1911, including in addition to the data on field crops, abstracted on page 429 of this issue, brief notes on the work with cattle, mules, and hogs.

## NOTES.

---

**Georgia College and Station.**—Recent appointments in the college include Charles A. Whittle as editor-librarian, C. M. Kiger as tutor in horticulture, G. E. Rice as a district corn club agent vice G. M. Gay, and H. E. Carpenter as instructor in animal husbandry.

The station live stock and hay barn was struck by lightning on the evening of September 4, causing a loss of the barn, about 15 tons of hay, and several adjoining structures. The loss was covered in part by insurance.

**Massachusetts College and Station.**—Recent appointments in the college include the following: W. D. Clark, of the Pennsylvania College and Station, as professor of forestry; O. A. Morton as extension professor of agricultural education; A. A. Brown as instructor in poultry husbandry; W. W. Chenoweth as instructor in pomology; Samuel Coons as instructor in dairying; E. M. McDonald as instructor in agronomy; Arthur T. Dailey as supervisor of extension courses; and E. L. Morgan as community field agent. F. W. Morse has been designated acting director of the station, beginning October 1.

**Nebraska University and Station.**—R. K. Bliss, of the Iowa College, has been appointed professor of animal husbandry and animal husbandman; W. J. Morrill professor of forestry and forester; and G. C. White, of the Missouri University and Station, adjunct professor of dairy husbandry, vice W. L. French, resigned.

**New Hampshire College.**—Dr. Edward T. Fairchild, superintendent of public instruction in Kansas, has been appointed president.

**Cornell University and Station.**—John Craig, professor of horticulture since 1903, died August 12 at Siasconset, Mass. Professor Craig was born at Lakefield, Quebec, in 1864, and educated at McGill College and the Iowa College, graduating from the latter institution in 1887. For about 12 years he served as horticulturist at the Central Experimental Farm at Ottawa, Canada, returning to Iowa in 1899 to become professor of horticulture. In 1900 he was appointed professor of extension teaching in Cornell, relinquishing this position three years later to accept the chair of horticulture.

Professor Craig was the author of a revised edition of *Practical Agriculture* and a contributor to the *Cyclopedia of American Horticulture*, as well as the author of numerous station publications and articles in agricultural journals. He had been editor of the *National Nurseryman* for several years, and at the time of his death was secretary of the American Pomological Society.

He was especially well known in the field of pomology, having a wide acquaintance and being in much demand as a judge at exhibitions. He was also much interested in nut culture, chairman of the nomenclature committee of the American Sweet Pea and American Peony Societies, and a fellow of the Royal Horticultural Society of Great Britain.

**Ohio Station.**—A. F. D. Wussow has been appointed assistant in the department of nutrition; J. S. Houser has been promoted to the position of associate entomologist.

**Porto Rico University.**—The college of agriculture and mechanic arts opened its new building to students September 23. The initial enrollment of the year was 172, of whom 22 are in the agricultural courses.

**Rhode Island Station.**—Director H. J. Wheeler has tendered his resignation to take effect December 1.

**Utah College and Station.**—The extension work has been reorganized with Dr. E. G. Peterson as director and John T. Caine, III, as assistant director in charge of field parties. Robert J. Evans, Ph. D. (Cornell, 1912), has been appointed agronomist in the station in charge of arid farms and will also assist in the extension work. Dr. J. E. Greaves, associate chemist, has taken over Dr. Peterson's work in bacteriology as professor of bacteriology and bacteriologist, and H. E. McNatt has been appointed assistant animal husbandman in the college and station to succeed Professor Caine. G. M. Turpin resigned October 1 as poultryman to accept a similar position in the Iowa College.

**Vermont College.**—A. K. Peiterson has been appointed instructor in botany in the college of agriculture, vice John P. Helyar, whose resignation has been previously noted; and R. T. Burdick, a 1912 graduate of Cornell University, has been appointed instructor in agronomy.

**Washington College and Station.**—H. B. Humphrey has resigned as vice director of the station to accept the position of head of the department of botany in the college. Robert C. Ashby, superintendent of the farmers' institutes, has been appointed professor of animal husbandry in the college and animal husbandman in the station. Dr. Ira D. Cardiff, of Washburn College, has been appointed professor of plant physiology and bacteriology in the college and plant physiologist in the station.

**Recent Federal Agricultural Legislation.**—Aside from the agricultural appropriation act, a summary of which has already been given (E. S. R., 27, p. 301), among the principal agricultural measures to be enacted at the recent session of Congress was the Plant Quarantine Act, approved August 20. Under this law nursery stock may now be imported only after a permit has been issued by the Secretary of Agriculture, when properly labeled, and when accompanied by a certificate of inspection from the country of export (or in case no official system of inspection is maintained in that country upon compliance with regulations prescribed by the Secretary). Notice of its arrival at a port of entry in this country must also be given to the Secretary, and its subsequent movements in interstate commerce or the District of Columbia reported until it has received inspection from the proper state official.

Similar regulations may also be promulgated as regards the importation of other plants, fruits, vegetables, seeds, etc., in case their unrestricted entry becomes prejudicial. Whenever deemed necessary in order to check the introduction of a new pest, importations may be excluded entirely from certain countries or of certain kinds of plants and their products, and any State may be quarantined as regards the shipment of affected products in interstate commerce. A foreign quarantine has already been put in force against the white pine blister rust and potato wart, and a domestic quarantine against Hawaiian products likely to carry the Mediterranean fruit fly.

The administration of the act is entrusted to a Federal Horticultural Board of this Department, consisting of C. L. Marlatt and A. F. Burgess of the Bureau of Entomology, W. A. Orton and Peter Bisset of the Bureau of Plant Industry, and G. B. Sudworth of the Forest Service. The act as a whole became effective October 1, and carries an appropriation of \$25,000.

Another inspection measure, passed August 24 and effective February 24, 1913, prohibits the importation for seeding purposes of grain and grass seed

which are deemed adulterated or unfit for seeding purposes because of excessive weed content.

An act approved August 3 establishes a standard apple barrel containing 7,056 cubic inches, and defines standard grades for the fruit on the basis of variety, size, and quality. Labeling the barrels remains optional, but the use of the designation "standard" in case the fruit or barrels do not conform to the requirements is deemed misbranding, and if done knowingly renders the packer or seller liable to a penalty of \$1 per barrel and costs. The act does not become effective until July 1, 1913.

Provision was made in the Post Office appropriation act for investigations by a joint committee of Congress of the practicability of federal aid in the construction of post roads, and also for cooperative work by the Secretary of Agriculture and the Postmaster General in road improvement with a view primarily to increasing the effectiveness of rural mail delivery. An appropriation of \$25,000 was allotted for the Congressional investigation, and this Department was granted \$500,000 for use in States or local communities contributing double the federal allotments.

Other legislation provides for the collection of additional cotton statistics, and an inquiry into the general conditions of farm and other labor. As an attempt to demonstrate the possibilities as to growing spineless cacti for forage, Luther Burbank was granted the use of not to exceed 12 sections of semiarid lands for 5 years with the privilege of purchasing these lands at from \$1.25 to \$2.50 per acre if successful. The Food and Drugs Act of 1906 was amended by extending its provisions to false and fraudulent claims on the package or label as to the curative or therapeutic action of drugs. The Public Health and Marine-Hospital Service was designated the United States Public Health Service, and its functions extended to include studies of the diseases of man, sanitation, and related questions.

**Association of Official Agricultural Chemists.**—The twenty-eighth annual convention of this association was held in Washington, D. C., September 16 to 18, with a registration of 184 members and visitors.

The president of the association, H. J. Patterson, delivered the annual address, which dealt primarily with the part played by the association in the formation of the present system of agricultural colleges, experiment stations, and the development of modern agriculture. Attention was drawn to the advanced position occupied by the agricultural chemist of to-day, as compared with his status years ago. Special emphasis was placed on the necessity of standardizing college degrees conferred in chemistry, and of the chemical investigator of the present day having a working knowledge of an allied science, such as bacteriology or plant pathology. In addition, it was pointed out that a cooperative spirit should prevail between the chemists in the laboratory, as this will have a tendency to develop initiative, stimulate research, and prevent the development of routine workers.

Assistant Secretary of Agriculture W. M. Hays presented the greetings of this Department. He pointed out the need that more scientific men, chemists and others, should be studying problems which relate to eugenics, and also advocated extension work in the sciences.

The referee and associate referee on phosphoric acid, H. D. Haskins and A. J. Patten, reported a thorough study of the official volumetric method for the determination of both the available and total phosphoric acid in basic slag phosphate and a further study of the citrate of ammonia magnesia-mixture method. In the determination of available phosphoric acid, using Wagner's method for making the citric solution of the slag, closely agreeing results were not obtained by the analysts. Of the various methods the optional volumetric method gave

the lowest results, and the gravimetric method (official) gave the highest results when sulphuric acid was used as a solvent. Further work is to be done on these methods, with the same kind of slag. The committee appointed at the last session to study the availability of the phosphoric acid in Thomas slag phosphate also rendered a preliminary outline of methods, accompanied by blueprints for field, pot, and cylinder experiments.

The referee on nitrogen, C. L. Hare, reported the results of further study of a method for organic nitrogen activity and on the Salle method for determining nitrogen in nitrates. Four out of 5 sets of results obtained with the neutral permanganate method for organic nitrogen activity were in close agreement, and showed fairly uniform results in the hands of different analysts, without reference to the material used. The results with the alkaline permanganate method were not so uniform, except with treated feathers and mixed fertilizers. The Salle method is deemed worthy of further consideration.

H. B. McDonnell, as referee on potash, reported the results of cooperative work, using kainit as the test material. The results obtained with the platinum method were very satisfactory. The cobalti-nitrite method was not considered reliable in its present form, and the results thus far obtained with the perchloric acid method were low. Changes in the method of making the solution were also tested, with practically the same results as in the official method.

The associate referee on the availability of potash, E. E. Vanatta, reported on several samples of fertilizers which were known to contain manure ashes, using the official and J. L. Smith methods. The solubility of potash from such sources seems to vary inversely with the degree of heat employed in the furnaces used for burning the manure, and if the furnaces are too hot an insoluble silicate of potash is in all probability produced. In the sample less than one-half of the total potash was soluble when the official method was used. The results of some analyses of twigs and leaves from the peach tree are also included. A proposed modification of the official method for availability of potash was adopted, likewise a suggestion for making pot or plat experiments with potash of known organic origin and with inorganic forms.

G. S. Fraps, the referee on soils, reported on acidity methods of extracting humus, and a comparison of the Rather with the official method. It was decided that these various methods be studied further.

As a result of cooperative work done with inorganic plant constituents the referee, W. H. McIntire, recommended that the associate referee, B. E. Curry, be instructed to pursue studies with the Schreiber method for sulphur during the coming year. Unsatisfactory results were obtained with the oxalate method for iron and aluminum, and it was recommended that further study of this method be discontinued. The molybdate method was adopted as official, and a further study is to be made of its extension to the determination of calcium as oxalate and magnesium as magnesium-ammonium phosphate.

Following the report of the referee on insecticides, S. D. Averitt, the chromate method for total lead oxid in lead arsenate was adopted as official. The provisional methods for the analysis of lead arsenate were changed in accordance with recommendation 7 of the referee in 1910 and adopted as official.

L. F. Kebler, chairman of the committee on the testing of chemical reagents, reported a decided improvement in quality in the chemical reagents obtained by the Bureau of Chemistry during recent years. Many chemists, however, are still too willing to accept chemical reagents as delivered without questioning their purity.

The committees on the unification of analytical methods, fats and oils, and food standards were discharged.

The referee on water, W. W. Skinner, reported the results of cooperative work, and recommended that the phenol sulphonic acid method for nitrites and the

reduction method for nitrogen as nitrates (optional) be adopted as official. The method for strontium and the colorimetric method for the determination of iodine and bromine are to be further studied.

A. S. Mitchell, associate referee on food adulteration, gave a résumé of the work conducted on food adulteration during the past year. W. E. Mathewson, associate referee on colors, recommended that the methods described for the qualitative separation of coloring matters be adopted provisionally and that work bearing on the separation and identification of these substances be continued.

A. H. Bryan reported on the proceedings of the Eighth International Commission for Uniform Methods of Sugar Analysis, held in New York September 10. The resolutions of the commission concerning the temperature of polarization and the use of a neutral bichromate of potash light filter cell were referred to the referee on sugar, W. E. Cross, for report at the next meeting. Following a recommendation from the associate referee on saccharin products, J. R. Chittick, the method for the determination of solids in molasses and other sugar products, by means of the refractometer, using Geerlig's table of equivalents and temperature corrections, but expressing the results as percentages calculated from the refractometer readings, was adopted as a provisional method.

The associate referees on vinegar and flavoring extracts, W. A. Bender and R. S. Hiltner, reported cooperative work in these subjects. A continuation of a study of the refractive index of the ether extract of paprika with particular regard for detecting added oils was reported by the associate referee on spices, R. W. Hiltz. He recommended that a method be devised for detecting an excess of seeds in paprika and that samples of prepared mustard be studied as to their crude fiber content. E. Clark, as the associate referee on baking powders, reported considerable difficulty in getting arsenic-free reagents for determination of arsenic in baking powders.

The associate referee on meat and fish, W. B. Smith, reported on the study of starch, ammonia, and nitrate determinations. He recommended that the Price method for starch be substituted for the Mayerhofer method, and the Folin method for the magnesium oxide method for estimating ammonia.

H. C. Gore, associate referee on fruit products, reported results of studies on the determination of malic and citric acid. With the Pratt method for citric acid duplicates were hard to obtain, as tartaric acid when present in considerable amounts seems to interfere. In the malic acid cooperative work the results obtained agreed well. A study was also made of the optical rotation of malic and tartaric acids, respectively, in the presence of varying amounts of uranium acetate.

As to fats and oils, H. S. Bailey, associate referee, reported the results of a cooperative study of the glycerol method for the saponification of fats, and compared various procedures with the official method. The provisional method for the preparation of samples, the Zeiss butyro-refractometer method, method 12 for the determination of free fatty acids, the Halphen reaction for cotton-seed oil, the Baudouin test for sesame oil, and the Villavecchia test for sesame oil, all as given in Bulletin 107, revised, of the Bureau of Chemistry, were adopted as official.

The Emery method for the detection of added beet fat in lard, and the glycerin method for the preparation of fatty acids for use in the titer test, were made provisional, as was also the use of 75° as the temperature for use in the determination of the specific gravity of high melting-point fats.

A. E. Paul, as the associate referee on dairy products, reported a further study of his method for extracting fat from milk, cream, ice cream, evaporated milk, and sweetened condensed milk. The associate referee on cereal products,

H. L. White, reported cooperative work with methods for the estimation in wheat flour of soluble carbohydrates, gluten, gliadin, edestin and leucosin, amid nitrogen, nitrous nitrogen, moisture, and acidity of watery extract.

As regards condiments other than spices, W. J. McGee, associate referee, reported cooperative work done almost wholly with tomato catsup. He recommended a method for the determination of lactic acid and the adoption provisionally of methods for the analysis of tomato products. The cooperative work on cocoa products, as reported by the associate referee, W. L. Dubois, concerned the determination of fat in chocolate, and total solids, crude starch, and casein in milk chocolate. H. E. Barnard, associate referee on preservatives, reported that his work had been almost wholly devoted to the detection and estimation of formic acid, which he considered more important at present than the study of better known preservatives.

The report of H. C. Lythgoe, associate referee on water in foods, dealt with the results of a comparative study between the official and vacuum methods, using different dehydrating agents, of which phosphorus pentoxid seemed to be the most feasible. H. M. Loomis, associate referee on heavy metals in foods, reported on the determination of tin in foods, principally by the Doolittle and Lourie and the Schreiber and Tabor methods.

The referee on the separation of nitrogenous bodies (meat proteins), A. D. Emmett, reported that the Kjeldahl-Gunning-Arnold method gave equally good results as the Kjeldahl method for total meat proteins. Additional data on soluble, insoluble, and coagulable nitrogen, creatin, and creatinin in meats and meat extracts were included in the report. The associate referee on vegetable proteids, T. B. Osborne, pointed out that present knowledge of the quantitative methods available does not yet justify definite recommendations. In view of the recognized difficulties, extended investigations were advocated, and a brief outline of a plan presented for undertaking them. A committee was appointed to consider these recommendations.

The associate referee on dairy products, L. I. Nurenberg, dealt with tests for distinguishing between raw and pasteurized milk and some recently proposed reactions for detecting old milk, viz, Schardinger's, Rothenfusser's, benzidin, and alcoholic precipitation (coagulation) with a reagent containing alizarin for approximating acidity. Bacterial counts were made in conjunction with the tests. Recommendations were made that the formaldehyde-methylene blue reaction, the methylene blue reaction, and the 6S-per cent alcohol precipitation method be further studied.

The referee, W. J. Jones, and associate referee, C. S. Cathcart, reported cooperative work on the analysis of feeding stuffs, which dealt mainly with methods for determining acidity and the petroleum-ether method for fat. In the study of acidity no close agreement among the results was obtained, and no apparent definite relation could be found between the acidity figures and the amount of protein. The petroleum-ether method for crude fat showed closer duplicates among the majority of analysts than the official method, but in all samples a lower average result. The official method is considered easier to conduct and to allow more perfect and rapid drying of the extract, but the petroleum-ether method more nearly gives the real amount of fat present, and was recommended for further study.

L. F. Kebler, the referee on medicinal plants and drugs, discussed methods of sampling and analysis, and the inadequate standards of the present time. Special stress was laid on securing proper samples and on the fact that sampling must be modified according to the nature of the goods to be tested. In drawing conclusions, all available means, such as physical, organoleptic, chemical, mechanical, and microscopical must be enlisted.

G. W. Hoover, associate referee on medicated soft drinks, reported satisfactory results in cooperative work in the determination of the constituents caffeine, cocain, phosphoric acid, and total solids. W. O. Emery, associate referee on synthetic drug products, reported that in analyses of headache tablets a method had been devised for the estimation of caffeine, acetanilid, quinin, and morphin in the same preparation. Aspirin was also studied in regard to melting point, either alone or in admixture with salicylic acid. Salol was estimated satisfactorily with a standardized bromin solution. A. G. Murray reported cooperative work on the estimation of nitroglycerin in medicinal tablets, and H. E. Buchbinder on similar work with the Eaton method for morphin.

At the suggestion of W. D. Bigelow, a committee was appointed to edit a new issue of the official methods of analysis. Resolutions were adopted in memory of the late Director M. A. Scovell, of the Kentucky Station, and Prof. H. A. Weber, of Ohio State University.

The papers read during the session were as follows: A Proposed Modification of the Official Method for Determining Humus, by O. C. Smith; Application of the Ammonium Carbonate Method for the Determination of Humus to Hawaiian Soils, J. B. Rather; Note on the Analysis and Valuation of Maple Sugar, A. H. Bryan; A Proposed Method for the Determination of Tartaric Acid in Wines and Grape Juice, B. G. Hartman; The Composition of Vanilla Extract From Tahiti and Fiji Beans, A. L. Winton and E. H. Berry; A Probable Method for the Estimation of Optically Active Oils in Extracts, C. F. Poe; A Method for the Detection of Caramel in Tincture and Extract of Ginger, R. S. Hiltner; The Chloral Hydrate Test for Charlock, A. L. Winton; Determination of Starch in Meat Products, E. M. Bailey; The Modified Babcock Test for Fat in Sweetened Dairy Products and Ice Cream, J. O. Halverson; Determination of Lead in Cream of Tartar and Baking Powders, Paul D. Potter; Determination of Nitrogen Activity by the Modification of the Neutral Permanganate Method, J. M. McCandless; A Study of the Lead Number of Asafoetida and Allied Products, E. C. Merrill; Estimation of Morphin, H. E. Buchbinder; Comparison of Values Obtained for Refractive Indices of Aqueous Solutions of Ethyl and Methyl Alcohol, B. H. St. John; and Determination of Camphor by the Hydroxylamin Method, E. K. Nelson.

The officers elected for the coming year were as follows: Honorary president, H. W. Wiley, Washington, D. C.; president, G. S. Fraps, College Station, Tex.; vice president, E. F. Ladd, Agricultural College, N. Dak.; secretary, W. D. Bigelow, Washington, D. C.; additional members of the executive committee, C. H. Jones, Burlington, Vt., and R. N. Brackett, Clemson College, S. C.

**Agricultural Chemistry at the Eighth International Congress of Applied Chemistry.**—This congress was held in Washington and New York, September 4 to 13, under the patronage of the President of the United States. The papers presented before the section of agricultural chemistry were as follows: Factors Influencing the Composition of the Blood of Steers, P. F. Trowbridge and L. D. Haigh; Changes in the Composition of the Dairy Cow During Fattening Period, P. F. Trowbridge; Mineral Constituents of the New Born Calf, A. G. Hogan; Composition of Beef Fat as Influenced by Age and Condition of the Animal and Location in the Body, L. E. Morgan; A Study of the Cost of Maintenance and Growth and the Changes in the Composition of the Mature Beef Animal During the Fattening Period, C. R. Moulton; A Study of the Variations in Chemical Composition of the Timothy and Wheat Plants During Growth and Ripening, L. D. Haigh; Some Factors Influencing the Quantitative Determination of Arsenic in Soils, J. E. Greaves; Organic Phosphorus of Soil, J. Stewart; Plasticity of Clay, J. Stewart; The Composition of the Loess Soils of the Transition Region, F. J. Alway; Experiments with Reinoculation of Steamed Soils,

T. L. Lyon and J. A. Bizzell; Conservation of Phosphorus in the Urine, P. E. Browning; The Effect of Sodium Manures on the Percentage of Sugar in Certain Plants, B. L. Hartwell and P. H. Wessels; A Study of Soil Potassium, B. E. Curry and T. O. Smith; Composition and Digestibility of the Ether Extract of Fodders, G. S. Fraps and J. B. Rather; The Composition and Digestibility of the Chloroform Extract of Plants, G. S. Fraps and J. B. Rather; Soil Potash and Phosphoric Acid and Their Relation to Pot and Field Experiments, G. S. Fraps; The Effect of Fertilizers on the Composition of the Asparagus Plant, F. W. Morse; Calcium Arsenite as an Insecticide, E. B. Holland and J. C. Reed; The Combustible Gases Excreted by Cattle, J. A. Fries; The Metabolism of Cattle When Standing and Lying, H. P. Armsby and J. A. Fries; Error in the Babcock Butter-Fat Test of Fresh Milk Caused by Improper Diameter of Test Bottle Necks, J. C. Manchester; Field Test With Fertilizers, H. A. Huston; The Manganese Present in the Normal Animal Body, G. Bertrand and F. Medigreceanu; Use of Manganese as a Catalytic Fertilizer, G. Bertrand; Use of Sulphate of Aluminum as a Catalytic Fertilizer, G. Bertrand and H. Agulhon; Use of Boron as a Catalytic Fertilizer, H. Agulhon; The Inheritance of a High Starch Content in Potato Tubers, P. de Vilmorin and F. Levallois; Agro-geologic Study of Manganese, P. Nottin; Use of Zinc as a Catalytic Fertilizer, M. Javillier; Researches in Regard to Inorganic Fertilizers for Sugar Beets, A. Vivier; The Inheritance of Certain Imperfections in Gluten, L. Vuafart; Effect of Bichromate of Potash upon Milk when used as a Preservative, M. Vuafart; Nitrogen and Phosphoric Acid in Wheat and Wheat Flour, L. Vuafart; The Effect of Static Electricity upon the Development, Yield, and Composition of the Sugar Beet, R. Truka; The Fertilizing Effect of Palmaer Phosphate on Peat Soils, H. von Feilitzen; Remarks on the Theory Concerning the Action of Fertilizers, A. Rindell; The Relative Effect on Plant Growth (a) of Sodium Carbonate, and (b) of Imperviousness in Soils, J. W. Leather; Determination of Permeability of Soils to Water, J. W. Leather; Contribution to the Colloid Chemistry of Milk, G. Wiegner; Stimulation of the Action of Calcium Cyanamid upon the Yield of Cultivated Plants by Iron, A. Stutzer; The Composition of Kelps, J. W. Turrentine; The Salines of the United States as a Source of Potash, J. W. Turrentine, R. F. Gardner, and A. R. Merz; Organic Soil Constituents in Their Relation to Soil Fertility, O. Schreiner; Some Constituents of Humus, E. C. Shorey; Effect of Histidin and Arginin as Soil Constituents, J. J. Skinner; Normal and Abnormal Constituents of Soil Organic Matter, E. C. Lathrop; Biochemical Factors in Soils, M. X. Sullivan; The Extraction of Potash from Silicate Rocks, W. H. Ross; Alunite as a Source of Potash, W. H. Waggaman; Radioactivity of Soils, R. B. Moore; The Use of Ground Rocks and Ground Minerals as Fertilizers, W. O. Robinson and W. H. Fry; The Chemical Composition of Important Soil Types East of the Mississippi, W. O. Robinson; Sponge Spicules in Certain Soils, Comparison of Rock Grinding With Balls and Cylinders, and Movement of Soil Moisture, R. O. E. Davis; Distribution of Fine Particles in the Soil, R. O. E. Davis and C. C. Fletcher; The Composition of the Soil Solution, F. K. Cameron; The Role of the Lysimeter in Soil Solution Studies, F. K. Cameron; The Phosphate Deposits of Continental North America, L. P. Brown; The Effect of Lime upon the Alkali Tolerance of Wheat Seedlings, J. A. LeClerc and J. F. Breazeale; Behavior of Amino Acids in the Soil, S. L. Jodidi; Soil Exchange Experiments on the Composition of Wheat, J. A. LeClerc and P. A. Yoder; Factors Relating to the Availability of Nitrogenous Plant Foods, J. G. Lipman, A. W. Blair, I. L. Owen, and H. C. McLean. The officers of the section were Frank K. Cameron, president; H. J. Wheeler, vice president; and J. A. Le Clerc, secretary.

The Ninth International Congress is to be held in 1915 in Russia.

## CONTENTS OF VOL. XXVII, NO. 6.

---

	Page.
Recent work in agricultural science.....	501
Notes.....	600

### SUBJECT LIST OF ABSTRACTS.

#### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Studies in protein hydrolysis, Foreman.....	501
Investigation of proteins, Obermayer and Wilhelm.....	501
Following proteolysis in cheese with the formol-titrametric method, Gratz....	501
A brief investigation on the estimation of lecithin, Collison.....	502
Tests of the behavior of pentoses in fermenting mixtures, Cross and Tollens....	502
The mannit obtained from asparagus juice, Tollens.....	502
Studies on oxidizing enzymes, Bernard and Welter.....	502
The von Lorenz method for determination of phosphorus, Neubauer and Lücke.....	503
Estimation of nitrites in potable waters, Elsdon.....	503
Determination of calcium in the presence of magnesium, Carron.....	503
Determination of soluble arsenic in lead arsenates, Curry and Smith.....	504
Determination of saltpeter in meat, Tillmans and Splittgerber.....	504
Detection of alum in flour and bread, Lenz.....	504
Determination of the tin in tinplate used for canning food, Beveridge.....	505
Detection of saponin in beverages and foods by the hemolytic method, Sormani.....	505
Detection of saponin, Rühle.....	505
Behavior of milk to ammonium sulphate and method for lactose, Salkowski....	506
In regard to the fat of woman's milk, Arnold.....	506
The composition and examination of cow's and goat's milk, Alpers.....	506

	Page.
Enzym reactions for differentiating boiled from raw milk, Gröger.....	506
Are alkalinity and peroxidase synonymous? Kooper.....	507
In regard to the guaiac test, Schern and Schelihase.....	507
Source of error in the determination of the Polenske number, Arnold.....	507
A new method for determining sugar, Bang.....	507
The Andrlík urea method of polarization for cane products, Cross and Taggart..	508
Determination of sucrose in cane molasses, Ogilvie.....	508
[Report of the chemists], Vinson and Ross.....	508
Commercial methods of canning meat, McBryde.....	508
How to pack hominy free from black discoloration, souring, or starch hydrolysis.	508

## METEOROLOGY—WATER.

How about the weather? Schmucker.....	509
The moon and the weather in 1912, Hinselmann.....	509
Influence of reservoirs on climate.....	509
A contribution to the sums of temperature in phenology, Hegyfoky.....	509
Report of the Chief of the Weather Bureau, 1910-11.....	509
Meteorological observations at the Massachusetts Station, Ostrander et al.....	510
Report on weather forecasts, 1911, Gilchrist.....	510
The weather of 1911, Gilchrist.....	510
Variations in our climate, MacDowall.....	510
The drought of 1911, Kershaw.....	510
The average annual distribution of rainfall in Hungary, 1901-10, Héjás.....	510
Character of the summer rains of North Germany, Hellmann.....	510
Snow limits in different climates, Paschinger.....	510
The value of snow surveys as related to irrigation projects, Thiessen.....	510
The winds of the United States and their economic uses, Day.....	511
Subsoil water of central United States, McGee.....	511
On the transport of mud by a river in flood, Steel.....	511
Experiments on the removal of manganese from ground water, Thiesing.....	511
Influence of the hardness of water on its suitability for drinking purposes.....	511
The hygienic value of soft water.....	512
Disinfection of drinking water with chlorid of lime, Grimm.....	512
Wholesome water in the country, Billings.....	512
Sewage disposal in rural districts, Rodwell.....	512
Sewage treatment.—Advantages of land over artificial schemes, Manley.....	512
Sewage and the farmer, Sedgwick.....	512

## SOILS—FERTILIZERS.

Important American soils, Bonesteel.....	512
New Jersey soils in their relation to fertility and crop production, Lipman..	513
Geological maps before the German Agricultural Council, Jentzsch.....	513
Constitution of concretions in red soils of northern Italy, Blanck.....	513
Chemical and physical nature of red soils, Blanck.....	513
The origin of sea marshes, Schütte.....	513
Analyses of soils of German Southwest Africa, Grimme.....	513
Pumice soils, Aston.....	513
Rock and soil in relation to plant nutrition, Blanck.....	513
Acid excretion of roots and the solubility of plant food, Pfeiffer and Blanck..	514
Action of different solvents on the plant-food constituents, Engels.....	514
Value of plant constituents as dependent on solubility, Maschhaupt and Sinnige..	515
Remarks on absorptive saturated and unsaturated soils, Rindell.....	515
Relation of evaporation to water content of soil at wilting, Brown.....	515
Salt content of drainage waters of the polders of North Netherlands, Berkhout..	515
Influence on soil temperature of additions of sand to moor soils, von Fellitzen..	516
Soil bacteriology in agriculture, Lipman.....	516
Relation of soil bacteria to evaporation, Hoffmann.....	516
The nitrogen cycle in the soil, Russell.....	517
Nitrifying and ammonifying powers of North Carolina soils, Stevens et al.....	517
Investigations on nitrogen fixation of <i>Azotobacter chroococcum</i> , Rösing.....	517
The influence of stall manure upon the bacterial flora of the soil, Temple.....	518
Earthworms and the fertility of the soil, Beaugé.....	518
[Maintenance of soil fertility in China, Korea, and Japan], King.....	518
How may fertilizer experiments be improved? De Jong.....	519

	Page.
The discrepancy between the results obtained in pots and in the field, Cohen.	519
Loss of fertilizer constituents in drainage water, Blair.	519
Sodium nitrate, calcium nitrate, and calcium cyanamid on moor soils, Rindell.	519
The present status of the artificial nitrogen fertilizer industry, Dafert.	519
The nitrate of soda industry of Chile, Diaz-Ossa.	519
New methods in the ammonia industry, Hölbling.	520
[Nitrogenous fertilizers derived from the air].	520
Action of organic compounds as modified by fertilizers, Schreiner and Skinner.	520
Effect of the "wet process" on availability of nitrogen, Hartwell and Pember.	520
Relation of active potash to pot experiments, Fraps.	520
Mica as a source of potash for plants, Blanck.	520
Preparation of superphosphate with sulphur dioxid and chlorin, Sestini.	521
Guano supply of French Somaliland, Schulz.	521
Fertilizer from city refuse.	521
The utilization of sewage sludge.	521
Annual report on fertilizers August 1, 1911, Ross.	521
Analyses of commercial fertilizers, Scovell and Curtis.	521
Russian fertilizer situation.	521

## AGRICULTURAL BOTANY.

Chemical effects of radiant energy in plant processes, Spoehr.	521
Rhythm in plant development, Klebs.	522
Transpiration in succulent plants, Delf.	522
The water relations of halophytes and sclerophylls, Lloyd.	522
The influence of methylene blue on the respiration of plants, Palladin et al.	523
The influence of methylene blue on the respiration of plants, Hübbenet.	523
The freezing of plants, Molisch.	523
Effects of severe frosts on vegetation in active growth, Butters and Rosendahl.	523
Chemical protection of plants against freezing, Maksimov.	524
Germination of seed as affected by sulphuric acid treatment, Love and Leighty.	524
The influence of the seed upon the size of the fruit in <i>Staphylea</i> , II, Harris.	524
Some points in the morphology and physiology of fasciated seedlings, Reed.	524
Transformation of reserve substance in <i>Dahlia variabilis</i> , Sciacca and Zerilli.	525
Displacement by water of nutritive substances in plants, André.	525
Significance of protein assimilation in the life processes of plants, Ehrlich.	525
The building of protein by yeasts and mold fungi, Ehrlich.	525
Carbon assimilation as affected by organic acids and their salts, Ravin.	525
The formation of saccharose in sugar beets, Strohmmer, Briem, and Fallada.	526
The rôle of catalase in plants, Zaleski and Rosenberg.	526
Total and nitric nitrogen in parasitic and saprophytic plants, Lutz.	526
The relation of some fungi to organic acids, Herzog, Ripke, and Saladin.	526
Studies on iron-storing Hyphomycetes, Lieske.	527
On arbutin in leaves of <i>Grevillea robusta</i> , Bourquelot and Fichtenholz.	527
Wood coloring in living spruce, von Tubeuf.	527
The influence of sea water on the distribution of plants, Harshberger.	527
Minnesota mushrooms, Clements.	528
Plant introduction for the plant breeder, Fairchild.	528
The present state of the mutation theory, Blaringhem.	528
<i>Enothera nanella</i> , healthy and diseased, De Vries.	528

## FIELD CROPS.

[Range improvement, plant introduction, and plant breeding], Thorner et al.	528
[Work at Sulphur Springs and Snowflake dry farms], Clothier and McOmie.	529
[Variety and manurial tests with cereals and root crops], Foulkes et al.	529
Field experiments in 1910, Tulaikov.	530
[Experiments at the Kaiser Wilhelm Institute for agriculture], Gerlach.	531
Irrigation experiments in 1909, Gerlach.	531
The water economy of dry-land crops, Kearney and Shantz.	531
Some misconceptions concerning dry farming, Chilcott.	531
Rotations in the corn belt, Smith.	531
Wheat and oats, Burgess.	531
Report on field trials with varieties of oats and wheat in 1909, Milburn.	531
Report on field trials on the manuring of seeds hay in 1909, Blackshaw.	532
[Fertilizer and variety tests with meadow hay, swedes, and potatoes].	532

	Page.
Trials with millets and sorghums in South Dakota, Hume and Champlin . . . . .	532
Alfalfa growing in Alberta, Fairfield and Hutton . . . . .	533
Varieties of barley . . . . .	533
Genetic studies of the genus <i>Brassica</i> , Kajanus . . . . .	533
Observations on the inheritance of characters in <i>Zea mays</i> , Burt-Davy . . . . .	533
Cooperative tests of corn varieties, Minns . . . . .	533
Cotton improvement on a community basis, Cook . . . . .	533
Fibers used for binder twine, Dewey . . . . .	534
Manuring of hops, Dyer . . . . .	534
Orchard grass seed from different countries, Stebler and Volkart . . . . .	534
Experiments on paddy cultivation 1909-1911, Coleman and Rama Chandra . . . . .	534
Growth of sugar beet . . . . .	534
Nitrogen fertilization and the composition of sugar beets, Sándor . . . . .	534
Manuring of swedes . . . . .	535
The production of new and improved varieties of timothy, Webber et al. . . . .	535
Correlation and inheritance in <i>Nicotiana tabacum</i> , Hayes . . . . .	535
The prospects for wheat cultivation in Natal, Sawyer . . . . .	536
Results of seed tests for 1911, Taylor . . . . .	536
Purity and germination of seeds sold in North Carolina, Tillman . . . . .	536
Eradication of charlock and wild mustard, Sándor . . . . .	536
Johnson grass control, Wilson . . . . .	536

## HORTICULTURE.

The present status of horticulture in the Philippines and its outlook, Wester . . . . .	537
Report of the Government Horticultural Gardens, Lucknow, 1912, Hailey . . . . .	537
Report of the Government Botanical Gardens, Saharanpur, 1912, Hailey . . . . .	537
The vegetable garden, Blair . . . . .	537
Annotated list of Philippine vegetables, Wester and Barrett . . . . .	537
Annotated list of Philippine fruits, Wester and Barrett . . . . .	537
Recent plant introductions into the Philippines, Wester . . . . .	537
Marcottage: Its utilization in the Tropics, Boyle . . . . .	537
Anonaceous fruits and their propagation, Wester . . . . .	537
Promising new fruits, Taylor and Gould . . . . .	537
Orchard notes, Bonns . . . . .	537
Apple growing, Burritt . . . . .	538
Apple growing in the Pacific Northwest, Lewis et al. . . . .	538
The fibro-vascular system of the apple and its junctions, McAlpine . . . . .	538
The fibro-vascular system of the pear, McAlpine . . . . .	538
Experiments with artificial root pressure, Vallejo . . . . .	538
[Peach culture] . . . . .	539
Artificial date ripening, Vinson and Ross . . . . .	539

The Weather Bureau and the cranberry industry, Cox . . . . .	539
Vines and vine culture, Barron . . . . .	539
The Oppenheim method of tying up vine shoots, Kober . . . . .	539
Early or late pruning, Ravaz . . . . .	540
Physiology of the graft.—Influence of stock on scion, Rivière and Bailhache . . . . .	540
The hybrid direct bearers in 1911, Desmoulin and Villard . . . . .	540
Report of the enological station up to November 31, 1910, De Zúñiga . . . . .	540
Report of the enological station of Haro for 1911, De Zúñiga . . . . .	540
Cacao experiments, 1911 . . . . .	541
Street trees, Levison . . . . .	541
Native trees as hedge plants, Green . . . . .	541

## FORESTRY.

Economic woods of the United States, Record . . . . .	541
Commercial guide to the forest economic products of India, Pearson . . . . .	541
Experiments with jack pine and hemlock for mechanical pulp, Thickens . . . . .	541
Antiseptic treatment of <i>Pinus excelsa</i> and <i>P. longifolia</i> sleepers, Pearson . . . . .	542
Harvesting and preparation of balata in French Guiana, Boucher . . . . .	542
<i>Hevea brasiliensis</i> or Para rubber, Wright . . . . .	542
The influence of light on the quality of oak wood, Galland . . . . .	542
Establishment of mixed stands, Tiemann . . . . .	542

	Page.
Winterkilling of evergreens, Nash.....	542
Forest conditions in Indiana, Coulter.....	542
Tree planting by farmers, Tillotson.....	542
The business aspect of National Forest timber sales, Woodbury.....	543
Report on forest administration of Central Provinces, 1910-11, Forteach et al.....	543
Report of forest circles in Bombay, including Sind, 1910-11, Napier et al.....	543
Progress report of forest administration in Coorg for 1910-11, Tireman.....	543

## DISEASES OF PLANTS.

Some recent work on fungus diseases of plants, Pammel.....	543
Fungus diseases in Iowa for the year 1911, Pammel.....	543
Report on plant diseases observed during 1911, Rostrup and Ravn.....	543
Report on vegetable pathology, Tryon.....	543
Studies of parasitized leaf tissue, Reynolds.....	543
Studies of some new <i>Citromyces</i> , Bainier and Sartory.....	543
On root tumors, Stift.....	544
The causes of beet blight, Peters.....	544
Investigations of the potato fungus <i>Phytophthora infestans</i> , Jones et al.....	544
Ustilagineæ on <i>Andropogon sorghum</i> in America, Potter.....	545
Some diseases of sugar cane in the Hawaiian Islands, Van der Stok.....	545
Infection experiments with the powdery mildew of wheat, Reed.....	545
Notes on some apple diseases, Wolf.....	546
Canker diseases of apple trees, Probst.....	546
Two apple cankers, Fawcett.....	546
Apple scab infection, Wallace.....	546
Frost injuries to apples, Naumann.....	546
Gum diseases in citrus trees, Fawcett.....	546
A new species of <i>Pyrenomyces</i> , Naumow.....	546
The treatment of downy mildew, black rot, and powdery mildew, Lerou.....	546
Infection of the grape by downy mildew, Ravaz and Verge.....	547
The influence of weather on <i>Peronospora</i> disease of grape, Gerneck.....	547
A new parasite of the grape, Planchon.....	547

# EXPERIMENT STATION RECORD.

VOL. XXVII.

ABSTRACT NUMBER.

No. 6.

---

## RECENT WORK IN AGRICULTURAL SCIENCE.

---

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

**Studies in protein hydrolysis**, F. W. FOREMAN (*Jour. Agr. Sci.*, 4 (1912), No. 4, pp. 430-433).—As a result of this research it was found that by using dry salts for esterification, in place of the watery sirup which is usually employed, a great saving of time and trouble may be effected in the early stages of the process, and furthermore that a very satisfactory esterification may be obtained. This is due to the fact that alcohol when used will prevent the reverse effect of the small amount of water produced. The complete removal of water from such a sirup is prevented by the presence of an excess of free hydrochloric acid, and the removal of the esterification water may therefore be more efficiently secured when an alcoholic solution containing the ester hydrochlorids alone, as in the author's process, is evaporated.

It is further claimed for this process that owing to the solubility of the ester hydrochlorids in chloroform and the freedom of their solution from hydrochloric acid the presence of a small quantity of anhydrous baryta, without the addition of water, will efficiently liberate the esters from their hydrochlorids. The yields obtained are as high as those obtained by the older methods.

In regard to the investigation of proteins with the formol-titrametric method, F. OBERMAYER and R. WILHELM (*Biochem. Ztschr.*, 38 (1911), No. 3-4, pp. 331-343; *abs. in Zentbl. Expt. Med.*, 1 (1912), No. 4, pp. 157, 158; *Zentbl. Biochem. u. Biophys.*, 13 (1912), No. 1-2, p. 6).—It was noted that when adding a neutral solution of formaldehyde to an aqueous solution of a protein which reacted neutral to litmus, a strong acid reaction developed. According to this, the amino acids and ammonia are not the only substances which can be determined by the Sörenson method.

The tests were conducted with carefully purified proteins which gave a negative reaction with Nessler's reagent and only a faint brown tinge with the quinone test for amino acids. The results bring out the fact that the method will yield constants for certain classes of proteins, which are more or less characteristic. If the value found for total nitrogen by the Kjeldahl method is divided by the value obtained in the formaldehyde titration a figure is obtained which the authors term the amino index of the protein in question.

It was found that the amino index of globulin is greater than that of albumin. Globulin from horse serum had an index of 20 while albumin from the same source had one of 13. The figures for the proteins from the different mammalia were found to differ only slightly among themselves.

Following proteolysis in cheese with the formol-titrametric method, O. GRATZ (*Ztschr. Untersuch. Nahr. u. Genussm.*, 23 (1912), No. 8, pp. 379-384).—The course of proteolysis was followed in Emmental, Limburg, Edam, Camem-

bert, Roquefort, Gorgonzola and Liptau cheeses with the formol-titrametric method.

The results showed that the degree of protein degeneration can be determined with this method as well as with the precipitation method. One method, however, supplements the other. In this work the formol titration is conducted in the residue from the ammonia distillation and in which 50 cc. of cheese extract is diluted with 100 cc. of water and distilled with barium carbonate. The carbonates and phosphates remaining in the residue are removed by precipitation with 2 cc. of a saturated barium chlorid solution and 5 cc. of a one-fourth-normal barium hydrate solution. The mixture is then made up to 200 cc., filtered after standing for 15 minutes, and 100 cc. of filtrate neutralized with hydrochloric acid toward litmus and used for the formol-titration.

**A brief investigation on the estimation of lecithin, R. C. COLLISON** (*Jour. Biol. Chem.*, 11 (1912), No. 3, pp. 217-220).—According to the results obtained with brain and liver tissue it would seem that the straight extraction method with anhydrous alcohol and anhydrous ether is preferable to the acid-chloroform-water method which is recommended by Koch (E. S. R., 22, p. 411). The results obtained with the crude reagents and the acid-chloroform-water mixture were found to be uniformly higher, probably due to the inclusion of inorganic or other forms of nonlipoid phosphorus.

**Tests in regard to the behavior of pentoses in fermenting mixtures, W. E. CROSS and B. TOLLENS** (*Jour. Landw.*, 59 (1911), No. 4, pp. 419-428; *abs. in Zentbl. Biochem. u. Biophys.*, 13 (1912), No. 1-2, p. 59).—This work was carried out with arabinose, xylose, methyl pentoses, rhamnose, and extracts made from brewers' grains. These sugars were fermented in solutions containing dextrose and without dextrose. The ferment used was yeast. The nutrient solution in one case was yeast water and in the other one artificially prepared and containing very little organic matter.

The pentose solutions which were free from hexoses were stable, showing no change after a long time, and those solutions containing dextrose and yeast water were also not affected. On the other hand the solutions having the artificial nutrients present and hexoses showed a loss in pentose content after fermentation. The points made in the experiments are that pentoses during fermentation may be utilized for producing new cells when such products as yeast water contains are not present.

**The mannit obtained from asparagus juice, B. TOLLENS** (*Jour. Landw.*, 59 (1911), No. 4, pp. 429, 430; *abs. in Zentbl. Biochem. u. Biophys.*, 13 (1912), No. 1-2, p. 6).—Wichers and Tollens in the work previously noted (E. S. R., 24, p. 509) could not obtain mannit in crystalline form from recently pressed juice. They now find that if this juice is allowed to stand for a time small needle-shaped crystals, which have a melting point of 167 to 168° C. and are optically inactive in an aqueous solution but optically active in a borax solution, are obtained. The specific rotation as recorded with the borax solution indicated mannit.

**Studies on oxidizing enzymes, BERNARD and WELTER** (*Ann. Jard. Bot. Buitenzorg.* 2. ser., 10 (1912), pt. 1, pp. 1-58; *abs. in Chem. Abs.*, 6 (1912), No. 9, p. 1162).—Cleansed and sterile sea sand, pulverized glass, powdered pumice, and infusorial earth turn tincture of gualac blue in the presence of hydrogen peroxid. Gypsum, calcium oxalate, marble dust, and starch also produce a blue color, but it is not so pronounced. Starch gave the weakest reactions. The oxidation of hydroquinone and pyrogallol in the presence of hydrogen peroxid can be accomplished by various substances, but not by traces of iron or manganese.

“Starch paste with potassium iodid is not a suitable reagent for studying oxidases because hydrogen peroxid alone or organic peroxids set free active oxygen under these conditions. Bleaching of blued guaiacum is not due to reducing substances but to inhibiting effect of hydrogen peroxid on oxidases. Alcoholic solutions of guaiacum develop peroxid very rapidly. Only large pieces of gum with little surface exposure should be used. Saturated alcoholic solutions of the gum seemed to change less rapidly. Tannin interferes with both direct and indirect oxidase (peroxidase) action, this effect being prevented by precipitating tannin with hide powder. Certain fruits, as *Carica papaya*, give an oxidase test only after ripening. The juice of certain green fruits when treated with hide powder then gave the oxidase test. Standard color solution of indigo carmin was used to make comparative determinations of amounts of oxidases in various parts of the tea plant as judged by the depth of the blue color due to the oxidation of guaiacum.” “Direct oxidase is not an enzym in the strict sense of the term but is an organic peroxid as held by Bach and Chodat. The peroxidase from tea leaves is very resistant to heat and is not subsequently regenerated when allowed to stand. Mercuric chlorid, hydrocyanic acid, and solutions of mineral acids destroy the oxidizing action of tea leaves. Exposure to light seems to prevent formation of peroxid but has no effect upon the peroxidase preparation. Yeasts present in tea fermentation do not secrete any extracellular oxidases which are involved in the production of common tea.”

In regard to the von Lorenz method for the determination of phosphorus, H. NEUBAUER and F. LÜCKER (*Ztschr. Analyt. Chem.*, 51 (1912), No. 3-4, pp. 161-175).—By substituting acetone for alcohol and ether for washing the molybdate precipitate the cost of conducting this test can be much reduced.

The precipitate, which is obtained in the usual way, is collected in a Gooch crucible containing filter paper or on the Neubauer platinum sponge crucible, washed 4 times with a 2 per cent solution of ammonium nitrate and 3 times with acetone, and then placed in a vacuum desiccator at a pressure not greater than 150 mm. of mercury for  $\frac{1}{2}$  hour and weighed. If the weighing can not be done immediately, the crucible is placed in an ordinary desiccator over sulphuric acid until the weighing time. The results obtained compared well with those obtained by the usual method. The spent acetone may be recovered by dehydration with potassium carbonate.

Estimation of nitrites in potable waters, G. D. ELSDON (*Chem. News*, 105 (1912), No. 2739, p. 243).—“For the following reasons the author much prefers the Griess-Ilosvay reagent for testing for nitrites, both qualitatively and quantitatively: (1) The color is practically steady after standing about 2 hours, and it is easy to compare and match. (2) It is not affected by ferrous and ferric salts. (3) Only one solution has to be added, and this will keep for months without decomposition.

“The starch-iodid test only seems to have one good point, namely, that the solutions required are ordinary laboratory reagents.”

Determination of calcium in the presence of magnesium, E. C. CARRON (*Ann. Chim. Analyt.*, 17 (1912), No. 4, pp. 127-129; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 9, p. 460).—Much difficulty is experienced in the separation of calcium from magnesium by the usual methods, particularly where a large excess of magnesium is present. The following method is recommended as being an accurate one for this purpose:

“The solution of the chlorids—which may contain ammonium chlorid and ammonia—is concentrated to 60 or 80 cc. and made slightly alkaline. After the addition of 20 cc. of ammonium bisulphite solution—prepared by saturating

aqueous ammonia (22° B.) with sulphur dioxide—the liquid is heated to about 90° C. and, upon the appearance of a crystalline precipitate, 20 cc. of ammonia solution (22° B.) are added and the mixture is well stirred. The calcium sulphite, precipitated (in crystalline form) in accordance with the equations:  $\text{CaCl}_2 + 3\text{NH}_4\text{HSO}_3 + \text{NH}_3 = \text{CaS}_2\text{O}_3 + 2\text{NH}_4\text{Cl} + (\text{NH}_4)_2\text{SO}_3 + \text{H}_2\text{O}$ , and  $\text{CaS}_2\text{O}_3 + 2\text{NH}_3 + \text{H}_2\text{O} = \text{CaSO}_3 + (\text{NH}_4)_2\text{SO}_3$ , is allowed to settle for an hour and is then filtered off, washed with hot, slightly ammoniacal water, dried, calcined in a muffle, and weighed as calcium sulphate; before incineration, the filter paper is moistened with a saturated solution of ammonium sulphate containing free sulphuric acid to prevent the formation of calcium sulphid. After the complete expulsion of the free and combined sulphurous acid from the filtrate, the magnesium is determined by precipitation with sodium phosphate in the usual manner."

The method requires about 3 hours for each determination of calcium. Zinc, nickel, and cobalt when present do not influence the process. See also a previous note by Hinds (E. S. R., 26, p. 21).

A short method for the determination of soluble arsenic in commercial lead arsenates, B. E. CURRY and T. O. SMITH (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 3, pp. 198-201).—The official method for soluble arsenic oxide requires 10 to 11 days, so that to economize time the following method, which only takes about 2 days in all and will give results as total soluble arsenic, was devised:

An amount of moist commercial arsenate, corresponding to 2 gm. of dry substance, is placed in a flask with 500 cc. of water and agitated continuously in a thermostat at 20° C. for 18 hours by means of a hot-air engine. The mixture is then filtered and a small portion of the filtrate tested for arsenious oxide. If present, 200 cc. of filtrate is taken, some bicarbonate of soda and starch added, and titrated with a standard iodine solution. The solution is then treated with 5 cc. of sulphuric acid and 1 gm. of potassium iodide, evaporated to a bulk of from 40 to 50 cc., and then diluted to 150 cc. with water. If an excess of iodine is present, it may be removed by the addition of twentieth-normal sodium thiosulphate solution until no yellow color remains. The solution is now rendered slightly alkaline with sodium hydrate, then acid with dilute sulphuric acid, and alkaline again with sodium bicarbonate. The arsenite is then titrated with iodine solution, employing starch as the indicator. The solubility of lead arsenite for this procedure is less than it is in the official method, i. e., 0.151 with the former and 0.605 with the latter method. By deducting 0.151 from the results obtained with the method described the percentage of total soluble arsenic is obtained. The figures agree well with the official method when the results of both methods are corrected.

Determination of saltpeter in meat, J. TILLMANS and A. SPLITTGERBER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 2, pp. 49-56; *abs. in Ztschr. Angew. Chem.*, 25 (1912), No. 17, p. 852).—Tests made with the brucin-sulphuric acid method and the diphenylamin sulphuric acid method with commercial samples and samples prepared with known potassium nitrate content show that both methods are sufficiently accurate for ordinary work. Where exact results are required the Schösswig-Wagner method must be used. The literature is discussed.

Detection of alum in flour and bread, W. LENZ (*Apoth. Ztg.*, 26 (1911), No. 66, pp. 687-689; *abs. in Chem. Ztg.*, 35 (1911), No. 130, *Repert.*, p. 541).—The method is as follows: Two gm. of flour is mixed in a test tube with 3 cc. of water and 1 cc. of a 1 per cent solution of hematoxylin in 50 per cent alcohol, and then thoroughly shaken with 10 cc. of a saturated solution of sodium

chlorid. Pure flour settles to the bottom of the tube as a flesh-colored mass with a supernatant yellow fluid, while flour containing alum gives a slaty to blue-violet color.

For baked goods a microscopic examination of the ash is necessary. The ash is dissolved in hydrochloric acid, precipitated with ammonium hydrate, and redissolved in hydrochloric acid. To the resulting solution some potassium bisulphate is added. If the resulting precipitate contains octohedral crystals, which are characteristic of the salts of aluminum, alum is present. The crystals must be detected with the microscope.

A report on the determination of the amount of tin in tinplate used for canning preserved food, W. W. O. BEVERIDGE (*Jour. Roy. Army Med. Corps*, 16 (1911), No. 2, pp. 140-160, figs. 2).—This work presents the results of some examinations of tinplate destined for the manufacture of cans for holding preserved fruits, etc. As a preliminary test for the amount of erosion in a given can the author utilized the Walker gelatin-potassium ferricyanid test and the following method for determining the amount of tin present in the tinplate: Pieces of plate 1 sq. in. in size are subjected to the action of a warm solution of dry chlorine gas in carbon tetrachlorid or in fuming stannic chlorid to remove the tin, then washed and reweighed, the tin present in the sample thus being determined by difference.

For determining the variations in the coating of tin the author describes a method, from which the following conclusions are drawn: "(1) For cans to hold preserved meats, such as corned beef, the amount of tin per base-box of 112 plates measuring 14 by 20 in. should be at least 2.5 lbs., or an amount not falling anywhere below 0.0361 gm. to the square inch (both sides), to insure a fair distribution of the tin. (2) For cans intended for such foods as fruits, jams, etc., owing to their acid nature, and for meat extracts, essences, and highly salted foods, a layer of tin equivalent to not less than 3.5 lbs. per base-box, or 0.0506 gm. per square inch (both sides). (3) For dried foods such as biscuits, meal, etc., probably 2.25 lbs. or 0.0325 gm. per square inch would be quite sufficient. (4) In every case one-twentieth of the surface of the top, bottom, and sides respectively should be taken for analysis from the same can, and the lowest amount found on a given surface quoted. (5) In all cases the layer of tin should be continuous and as evenly laid as possible. (6) There should be no fissures and any surface extensively riddled with pin-holes as shown by the Walker test should lead to rejection of the plate. It is fair to state, however, that at the present time a certain number of pin-holes appear to be inevitable, but with improved methods of plating they are likely in the future to be almost entirely eliminated. (7) The custom of painting the outside of the cans to prevent rust is a good one, and should be continued."

Detection of saponin in beverages and foods by the hemolytic method, C. SORMANI (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 23 (1912), No. 11, pp. 561-566).—The author concludes that the hemolytic methods, especially Rusconi's procedure, yields far better results than the usual chemical methods for detecting saponin in foods, etc.

Detection of saponin, J. RÜHLE (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 23 (1912), No. 11, pp. 566-577).—Vamvaka's method for the detection of saponin and for differentiating saponin from glycyrrhizin is not considered accurate. The color reactions with concentrated sulphuric acid and Fröhde's reaction (100 cc. of concentrated sulphuric acid +1 gm. of ammonium molybdate) are not always reliable, while the reactions obtained with  $\alpha$ -naphthol, thymol, and purified oxgall, which are dependent upon the presence of sugar, are of no value at all. In these tests the hemolytic test was the only one which gave entirely satisfactory results.

The behavior of milk towards ammonium sulphate and a new method for determining lactose, E. SALKOWSKI (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 78 (1912), No. 2, pp. 89-95).—This article deals with the use of ammonium sulphate as a reagent for precipitating the proteins from milk for the purpose of determining lactose in the filtrate. The method is as follows: Fifty cc. of milk is placed in a wide-mouthed, graduated, stoppered glass cylinder of from 150 to 200 cc. capacity and treated with 17.5 gm. of ammonium sulphate, then shaken thoroughly, filled up to the 100 cc. mark with a saturated solution of ammonium sulphate in water, mixed, and filtered through a 16-cm. filter. In a few minutes enough filtrate is obtained for the polariscopic determination of lactose.

In regard to the fat of woman's milk, W. ARNOLD (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 9, pp. 433-440).—The chemical composition of the fat in woman's milk differs from that contained in cow's milk, not only in the amount of water-soluble substances present but also in the composition of these acids. Cow's milk fat contains a larger amount of butyric and less caproic acids, and a little caprylic acid, corresponding to a middle molecular weight of from 100 to 106, while the water-soluble fatty acids of human milk fat contain a larger amount of caprylic and caproic acid, and possibly of butyric acid, closely correspond to the acids of coconut fat, and have a molecular weight of 128.9. Furthermore, the oleic acid content of human milk fat is higher than that of cow's milk fat. A close agreement, however, is found among the non-volatile fatty acids (insoluble in water). Figures for the molecular weight varying from 259 to 262 were obtained. On the other hand, the iodine numbers of the nonvolatile fatty acids of human milk fat are higher than those of cow's milk fat. A mixture of 14 parts of coconut fat and 86 parts of hog fat (lard) gave analytical data which corresponded closely to those with the fat contained in human milk.

The composition and examination of cow's and goat's milk with particular reference to the refraction of calcium-chlorid serum, K. ALPERS (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 10, pp. 497-513).—The refraction of the calcium-chlorid serum of individual milks varied between 35.8 and 41.3° at a temperature of 17.5° C. In one case, however, where the milk came from an inflamed udder it was 34°, and the milk from cows in heat in some cases showed marked variations in composition. The daily variation of the refraction, however, never exceeded 1.4°. As an average refraction, from 126 samples of milk taken in the barn the figure 39.11° was obtained. This method, according to the author, is a very valuable one for detecting added water to milk, but care must be taken in all cases not to overrate its value.

With goat's milk the refractions were from 34.7 to 40.3, with an average of 38°. The average specific gravity of goat's milk was 1.03, the average fat content 4.3, and the fat-free dry substance 8.89 per cent.

The most important enzym reactions for differentiating boiled from raw milk, especially Schardinger's reaction, A. GRÖGER (*Die wichtigsten Enzymreaktionen zur Unterscheidung roher und gekochter Milch. Inaug. Diss., Univ. Leipzig, 1911, pp. 61*).—Although Rothenfusser's reaction with paraphenylenediamin hydrochlorid in the hands of skilled persons is a good method for differentiating boiled from raw milk, it can not be recommended for use by the laity. The preparation of a serum, however, in this method is not necessary, as the boiled milk after standing for a time with this reagent will show a positive coloration. Taking everything into consideration the author believes that the Webber-Arnold guaiac reaction should be given the preference. Schardinger's reaction, on account of its requiring a water bath, is only of use in the laboratory, and since the reaction is influenced by the presence of much acid (as in

colostrum and old milk) it is better to conduct it with an alcoholic methylene blue-formaldehyde solution. The reaction will not determine whether or not the cow is in a new period of lactation.

Are alkalinity and peroxidase synonymous? W. D. KOOPER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 1, pp. 1-13; *abs. in Ztschr. Angew. Chem.*, 25 (1912), No. 17, p. 853).—The degree of alkalinity, that is, the amount of normal sulphuric acid required to discharge the violet color produced by Rothenfusser's reagent for fresh milk, was 110.1 cc., and like the degree of the acidity of milk it varies. In colostrum the degree of alkalinity is greater than in normal milk, but the amount of sulphuric acid required falls as the period of lactation goes on. In goat's milk the alkalinity degree is higher (120) than in cow's milk. The author believes peroxidase and alkalinity synonymous.

In regard to the guaiac test, K. SCHERN and W. SCHELLHASE (*Berlin. Tierärztl. Wchnschr.*, 28 (1912), No. 13, pp. 221-223).—A discussion of Kühn's work (*E. S. R.*, 26, p. 712), with some additional data in regard to the influence of hydrogen peroxid on the test. It was found that when hydrogen peroxid is added to the milk the guaiac reaction is influenced considerably, but not when the guaiac-guaiacol reagent is employed. Boiled sterile milk, without regard to time, does not give a positive test with the guaiac-guaiacol reagent.

Source of error in the determination of the Polenske number, W. ARNOLD (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 8, pp. 389-391).—According to the author, the difficulties encountered lie not with the method but with the manipulator who neglects certain criterions laid down by the author, and which it is absolutely necessary to follow in order to get correct results. The method is described in detail.

A new method for determining sugar, I. BANG (*Lunds Univ. Årsskr.*, n. ser., Sect. 2, 7 (1911), No. 8, pp. 1-10, pl. 1).—The original Bang method is open to the objections that the titration solutions are very expensive, the copper solution is not stable, and an incorrect titration made with a copper solution can not be corrected. Attempts were made to displace the potassium sulphocyanid with a cheaper salt, and potassium chlorid was found to be a good substitute, it also forming colorless compounds with cuprous oxid, but had the disadvantage of being able to hold only small amounts of cuprous oxid in the solution. It was also noted in this work that better results—end point determination, etc.—could be obtained if the cuprous oxid was titrated directly and not the unreduced cupric oxid, as in the older method, consequently iodin 1/300-normal was selected instead of hydroxylamin.

The other solutions necessary are as follows: (a) Potassium bicarbonate 160 gm., potassium carbonate 100 gm., and potassium chlorid 66 gm. are dissolved in 700 cc. of water. The potassium bicarbonate is dissolved first, then the other salts, followed by 100 cc. of a 4.4 per cent copper sulphate solution, are added, and the solution filled to the 1,000 cc. mark with water. From this stock solution 300 cc. is diluted to the 1,000 cc. mark with a saturated solution of potassium chlorid. The latter solution, which is stable, should only be employed after standing for a few hours. (b) A solution of soluble starch, which consists of 1 gm. of soluble starch in a saturated solution of potassium chlorid.

The method is conducted as follows: Two cc. of the sugar solution, which is only one-sixth as strong as the old method calls for, is placed in a 100 cc. Jena flask, which has its upper rim removed, with 55 cc. of a copper solution. A rubber tube about 5 cm. long is pulled over the neck of the flask until it stands about two-thirds above the flask. The solution is boiled for 3 minutes, the tube clamped with a pinchcock, and the boiling continued to the end of the 3-minute period. The flask is then removed quickly from the flame and cooled, the rub-

ber hose removed, 1 cc. of 1 per cent starch solution added, and titrated with the iodine solution until from 2 to 4 drops produce a deep blue color which persists for from 20 to 30 seconds. The number of cubic centimeters of iodine solution used in the above titration, divided by 0.267, will give the amount of sugar present in milligrams.

The Andrlík urea method of polarization [in the Clerget process] for cane products, W. E. CROSS and W. G. TAGGART (*Internat. Sugar Jour.*, 13 (1911), No. 156, pp. 662-668; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 1, p. 37).—While urea and betain inhibit inversion to some extent at 28° C., the inhibition is not sufficient to allow a polarization to be made before inversion begins. At 20° inversion is much slower, but even at this temperature inversion takes place before a reading can be taken. "Clerget determinations were made, using pure sucrose solutions and a temperature of 20°, with the result that whereas the readings made in the ordinary way gave a value of 100 per cent, with the Andrlík polarization one of 99.41 per cent was obtained. When invert sugar was present, the ordinary Clerget value was 95.97, and using the Andrlík polarization, 99.75." At some lower temperature, perhaps 15°, the authors believe that the method could be employed, but such a temperature is impracticable in cane-producing countries.

Determination of sucrose in cane molasses and the double polarization method, using invertase and acid as hydrolysts, J. P. OGILVIE (*Internat. Sugar Jour.*, 14 (1912), No. 158, pp. 89-93; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 5, pp. 244, 245).—Continuing previous work (E. S. R., 25, p. 208) the invertase method has been extended to the examination of cane molasses.

The results show "(1) that if in the acid hydrolysis method, the generally employed procedure of using the alkaline direct polarization be adopted, the results may be too high to the extent of 0.4 to 1.3 per cent, according to the impurity of the product; (2) that if in the acid hydrolysis method the neutral direct polarization, in place of the alkaline, be used, the results are nearer the truth, but may again be too high, especially when much reducing sugars are present; and (3) that if in the acid hydrolysis method, the acid direct polarization, as recommended by Andrlík or Pellet, be used, then correct results are obtained."

In the case of beet-sugar molasses the presence of amino acids vitiates the polariscopic readings, while with cane molasses reducing sugars cause the changes. When basic lead acetate is present the right-handed rotation of a cane molasses solution is increased considerably, while after inversion when the solution is acid this activity is removed and levo-rotation is increased. Therefore the difference between the direct and indirect readings is not simply due to the hydrolyzed sucrose.

[Report of the chemists], A. E. VINSON and W. H. ROSS (*Arizona Sta. Rpt.* 1911, pp. 557-562, fig. 1).—An illustrated description of an electrical heater for ether extraction is given and its advantages over the old form of extraction apparatus enumerated. Analyses of Salton Sea water are also reported.

Commercial methods of canning meat, C. N. MCBRYDE (*U. S. Dept. Agr. Yearbook* 1911, pp. 383-390, pls. 3).—This deals with the historical development of the meat canning industry and describes briefly and illustrates the methods practiced at the present day.

How to pack hominy free from black discoloration and processed so it will keep free from souring or starch hydrolysis (*Canner and Dried Fruit Packer*, 34 (1912), No. 22, pp. 28, 30).—For canning lye hominy 1 bu. of corn is placed in a kettle with 1½ gal. lye. The kettle is filled to within 6 in. of the top with water and cooked for 30 minutes or until the hulls can be easily removed with the fingers. The hominy is run into the hulling machine, feeding slowly, and from there into a washing machine, feeding gradually with a continuous

flow of water. It is then brought to the boiling-out kettle where it is cooked for 30 minutes, stirring constantly during the process. The product is filled into No. 3 cans, 14 oz. to the can, covered with a brine made with 21 lbs. salt to 200 gal. water, and processed for 2 hours at 240° F.

### METEOROLOGY—WATER.

How about the weather? M. SCHMUCKER (*Wie Wird das Wetter? Dillingen, 1911, pp. 8+147*).—This book deals with a new theory of weather forecasting, based upon 25 years' observations on the relative motions of the sun, moon, and earth.

The moon and the weather in 1912, E. J. N. B. HINSELMANN (*Mond und Wetter im Jahre 1912. Hanover, 1912, pp. 17*).—The relation of the moon to the weather is discussed as well as weather predictions during 1912 based upon lunar observations. The value of such observations and predictions from the agricultural standpoint is also briefly discussed.

Influence of reservoirs on climate (*Prometheus, 23 (1912), No. 1161, Beibl., p. 66; abs. in Wasser u. Abwasser, 5 (1912), No. 9, pp. 376, 377*).—Observations, indicating a slight decrease and a moderation of extremes of temperature and an increase of fog as a result of evaporation from reservoirs, are reported.

A contribution to the sums of temperature in phenology, K. HEGYFÖKY (*Met. Ztschr., 29 (1912), Nos. 5, pp. 210-217; 6, pp. 272-281*).—The author concludes that sums of temperature without knowledge of the temperature variations and factors (sunshine, moisture conditions, etc.) determining them are of no value in phenology.

Report of the Chief of the Weather Bureau, 1910-11 (*U. S. Dept. Agr., Weather Bur. Rpt. 1910-11, pp. 260, pls. 4*).—This contains an administrative report reviewing the work of the Weather Bureau during the fiscal year ended June 30, 1911, at Mount Weather research observatory, on forecasts and warnings, and of the river and flood observations and reports, marine, instrument, and climatological divisions, and tables giving a general summary of the weather conditions in the United States by months during the year 1910, list of observing stations and changes therein during 1910, sunshine in 1910, details of excessive precipitation in 1910, monthly and annual meteorological summaries in 1910, monthly and annual amounts of precipitation in 1910, and monthly and seasonal snowfall in 1910-11.

“Special attention was given during the year to warnings for the benefit of shippers and growers of perishable products. Forecasts were sent out daily from a number of our larger stations, giving the probable temperatures likely to be encountered by perishable goods shipped in any direction.

“Substations were established in the cranberry marshes of Massachusetts, in the citrus fruit districts of Florida, and in some of the orchard districts of Washington, Oregon, Idaho, Utah, Colorado, and California. During the frost season special reports are sent from these substations to the forecast center, where they are used in the preparation of a special forecast in the afternoon or early evening, supplementing the regular morning forecast. By this means the growers are enabled to take such precautionary measures as are available to protect their crops. In Washington, Oregon, Idaho, Utah, Florida, and California the fruit growers smudge and fire when necessary, while in the cranberry regions the cranberry growers flood their bogs to prevent injury. In this line of work it has been the policy to furnish the individual with information particularly applicable to his orchard rather than to have him depend upon a general forecast that would apply to a large section but could not accurately cover the section in detail. Effort has also been made to encourage the grow-

ers to organize and employ protective measures in saving their crops from frosts and freezes. Thus far the work has been successful beyond expectation."

**Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER, R. N. HALLOWELL, and H. W. ANGIER** (*Massachusetts Sta. Met. Buls.* 281, 282, pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1912. The data are briefly discussed in general notes on the weather of each month.

**Report on weather forecasts, 1911, D. A. GILCHRIST** (*County Northumb. Ed. Com. Bul.* 18, 1912, pp. 82-84).—A brief summary is given of weather forecasts for agricultural purposes issued by the English Meteorological Office during the summer of 1911, and of records at Cockle Park, Northumberland, of the weather conditions for a few days immediately following the receipt of the forecasts. This summary shows that of 14 such forecasts 12 were correct.

**The weather of 1911, D. A. GILCHRIST** (*County Northumb. Ed. Com. Bul.* 18, 1912, pp. 84-90).—Observations on temperature, precipitation, and sunshine at Cockle Park and a number of other places in Northumberland are summarized. Observations on the temperature of cultivated and uncultivated soil are also given.

It was found that changes in temperature were less sudden in cultivated soil than in uncultivated soil. This is attributed to conservation of moisture in the cultivated soil. Samples taken at the same time showed 13.01 per cent moisture in the cultivated soil and only 9.53 per cent in the uncultivated soil.

**Variations in our climate, A. B. MACDOWALL** (*Symons' Met. Mag.*, 47 (1912), No. 554, p. 25).—A study of the number of frost days in winter at Greenwich from 1841 to 1911, by adding them for the 50-year periods ending 1891, 1892, and so on to 1911, indicated "a general decline in the figures and the last is the lowest. That is, the last 50 winters, September to May, had a smaller number of frost days than any previous 50 consecutive winters since 1841."

**The drought of 1911, M. KERSHAW** (*Ann. Sci. Bul. Roy. Agr. Col. Cirencester, 1911, No. 3, pp. 49-70, figs. 5*).—The nature and effects of this very severe drought, especially in the vicinity of Cirencester, are described. The total rainfall for the year was 23.31 in., 7.43 in. below the average. The total number of hours of sunshine was 1,715, 207 in excess of the average. The temperature of the growing season was much above the average.

**The average annual distribution of rainfall in Hungary, 1901-1910, E. HÉJÁS** (*Vizügyi Közlem.*, 2 (1912), No. 2; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Discases*, 3 (1912), No. 6, pp. 1267-1269).—This article contains a series of rainfall maps, describes the methods of making the rainfall observations, and discusses the distribution of rainfall in Hungary with reference to altitude, form, and position of the mountains, distance from the sea, and other topographic and physiographic features.

**Character of the summer rains of North Germany, G. HELLMANN** (*Sitzber. K. Preuss. Akad. Wiss.*, 1912, XVIII, pp. 282-303, figs. 4).—This is a study of the amount and distribution of these rains.

**Snow limits in different climates, V. PASCHINGER** (*Mitt. Justus Perthes' Geogr. Anst.*, 1912, *Ergänzungsh.* 173, pp. 93, pls. 5, fig. 1).—Detailed data regarding the permanent snow fields of the world are presented and their relation to climate is discussed.

**The value of snow surveys as related to irrigation projects, A. H. THIESSEN** (*U. S. Dept. Agr. Yearbook 1911, pp. 391-396, pls. 6, fig. 1*).—This article is based upon a snow survey of the Maple Creek watershed (E. S. R., 27, p. 415), near Provo, Utah. The value of such a survey from the standpoints of the irrigating farmer and the engineer is briefly discussed.

"A survey of this character is worth much more than the certainty it gives the irrigator regarding the future of his crop or the knowledge as to what crop he should plant. It eliminates his products from that class whose amount of production is more or less problematical. It tends to steady prices and, in addition to the taking away of these uncertain features, gives a crop, although not matured, a money value which it would not have, to such a great measure at least, if the water supply were not known."

**The winds of the United States and their economic uses**, P. C. DAY (*U. S. Dept. Agr. Yearbook 1911*, pp. 337-350, pls. 7, figs. 2).—This article contains and discusses a series of charts "showing the average hourly velocities of the wind and its direction throughout the various portions of the country and for special months of the year and hours of the day, with diagrams indicating the daily march of the winds and their variations at different levels." The data from which these charts were prepared are based mainly upon records for the 20-year period, 1891 to 1910, inclusive.

The economic use of the wind in windmills, for production of electrical energy, and in aviation is briefly discussed.

A more detailed paper on the subject is in course of preparation.

**Subsoil water of central United States**, W J MCGEE (*U. S. Dept. Agr. Yearbook 1911*, pp. 479-490).—This article is based upon data obtained through the crop reporters of the Department of Agriculture, and deals specifically with changes in level of water in wells in Illinois, Indiana, Iowa, Kentucky, Michigan, Minnesota, Missouri, Ohio, Tennessee, and Wisconsin.

"The number of wells showing change in water table ranges from 64.9 per cent in lower Michigan and 62.3 per cent in Wisconsin to 31.3 per cent in Missouri, averaging 52.1 per cent. The average lowering of water table during the period of observation ranges gradually down from 3.87 ft. in Wisconsin and 3.45 in Minnesota to 1.94 ft. in Tennessee, and then drops to only 0.95 ft. in Missouri. . . . The mean rate of lowering per decade for the 9 States excluding Missouri (1.315 ft.) is equivalent to a total lowering of 10.5 ft. in the 80 years which have elapsed since permanent settlement and cultivation began to extend into Illinois and Wisconsin and on into Iowa and Missouri." Although part of the lowering may be ascribed to special causes, "it seems clear that the records broadly indicate a secular lowering of the subsoil-water level, presumably due to clearing and cultivation of the land. . . ."

"The results are in accord with common knowledge—of the failing of springs and wells following settlement, of the dwindling and disappearance of brooks, of the advancing destruction by floods due to increased surface run-off during and after storms, of the increasing difficulty in obtaining domestic water supply for farms, villages, towns, and cities, of the steadily growing danger of crop loss through drought, of the increasing need for irrigation in the humid section."

**On the transport of mud by a river in flood**, T. STEEL (*Chem. News*, 105 (1912), No. 2743, p. 290).—This note gives observations on the amount of mud carried by the River Yarra, Victoria, in flood, and the composition of mud carried by the Tweed River, New South Wales, in flood. The latter showed on the basis of dry matter 1.16 per cent lime, 0.2 per cent potash, 0.36 per cent phosphoric acid, and 0.48 per cent nitrogen.

**Experiments on the removal of manganese from ground water**, THIESING (*Mitt. K. Prüfungsanst. Wasserver. u. Abwässer. Berlin*, 1912, No. 16, pp. 210-296, figs. 16).—From the results of these experiments the author concludes that manganese in the form of carbonate can be easily removed by aeration and filtration. The methods and precautions to be observed are fully discussed.

**Influence of the hardness of water on its suitability for drinking purposes** (*Prometheus*, 23 (1911), No. 1157, p. 207; *abs. in Wasser u. Abwasser*, 5 (1912),

No. 9, p. 380).—Reference is made to investigations by Wagner from which the conclusion is drawn that drinking water with a very high degree of hardness may be used without danger of injury to health. It is shown that many of the more common foods contain lime corresponding to a much higher degree of hardness than is often found in drinking water.

The hygienic value of soft water (*Sanit. Rec.*, 46 (1910), p. 448; *abs. in Wasser u. Abwasser*, 5 (1912), No. 9, pp. 380, 381).—In this article it is maintained that a high degree of hardness in water due to lime and inorganic substances is injurious to health, favoring goiter and rheumatism and hindering digestion.

Disinfection of drinking water with chlorid of lime, GRIMM (*Mitt. K. Prüfungsanst. Wasserver. u. Abwässer. Berlin*, 1912, No. 16, pp. 297–334).—Experience with this method of purification in the United States, England, and Germany is reviewed, and it is stated that this experience shows that two parts of chlorid of lime per million of water acting for 24 hours will completely disinfect only water which contains a small amount of organic matter.

Wholesome water in the country, F. H. BILLINGS (*Sci. Amer.*, 107 (1912), No. 2, p. 33, fig. 1).—The dangers of pollution of country water supplies and how they may be avoided are briefly discussed.

Sewage disposal in rural districts, A. RODWELL (*Surveyor*, 42 (1912), No. 1072, pp. 161, 162).—Simple methods adapted to country houses and small villages and towns are briefly described.

Sewage treatment.—Advantages of land over artificial schemes, J. MANLEY (*Surveyor*, 42 (1912), No. 1072, pp. 162, 163).—A number of examples, mostly English, of successful use of land treatment are cited.

Sewage and the farmer, W. T. SEDGWICK (*Sci. Amer.*, 107 (1912), No. 2, p. 38).—The author, discussing the waste of nitrogen in present methods of sewage disposal, the farmer's interest in the matter, the objection to the use of sewage on the farm, and the effect on fish of withholding sewage, reaches the general conclusion "that, except in the more arid portions of the United States, the utilization of sewage in farming does not seem likely to increase at present. Consequently, we may have to look in the future for our supplies of food more to the sea and less to the land."

## SOILS—FERTILIZERS.

Important American soils, J. A. BONSTEEL (*U. S. Dept. Agr. Yearbook 1911*, pp. 223–236).—As the dominant soil types, both as regards extent and crop adaptation, the author names and discusses (1) the Miami clay loam, the Marshall silt loam, the Carrington loam, and Fargo clay loam (E. S. R., 25, p. 625) of the Central States; (2) the Hagerstown loam (E. S. R., 25, p. 426) of the Appalachian Mountains and Plateau; and (3) the Norfolk fine sandy loam, the Orangeburg fine sandy loam (E. S. R., 26, p. 120), and the Houston black clay (E. S. R., 26, p. 517) of the coastal plain.

"These 8 soils will ultimately be found to cover nearly or quite one-fifth of the arable agricultural domain of the United States east of the ninety-eighth meridian, if the estimates based upon the extent of their acreage within areas covered by the soil surveys is not materially changed by the completion of additional surveys. Because of the great area of these few types, because each soil is preeminently adapted to the production of some great staple crop or group of such crops, because the problems attendant upon the production of each of such crops will be more easily solved upon such homogeneous soil areas than upon a diversity of minor types, the agriculture of the Nation is destined to be influ-

enced more and more by these soils and by the farmers engaged in their cultivation."

**New Jersey soils in their relation to fertility and crop production, J. G. LIPMAN** (*Ann. Rpt. N. J. Bd. Agr.*, 38 (1910), pp. 85-101).—This is a popular discussion of the subject.

**Geological maps before the German Agricultural Council, A. JENTZSCH** (*Internat. Mitt. Bodenk.*, 2 (1912), No. 1, pp. 3-44).—This has been noted from another source (*E. S. R.*, 25, p. 798).

**Regarding the constitution of concretions in red soils of northern Italy, E. BLANCK** (*Mitt. Landw. Inst. Breslau*, 6 (1911), No. 3, pp. 325-344).—The author reviews the literature on the origin and composition of typical laterite and red soils, and reports a study of the chemical composition of concretions formed in the red soils of Italy in relation to the parent rock and as compared with laterite concretions.

The results showed that the concretions of the red soils of Italy are composed largely of calcium carbonate and bear a close relation to the limestone rock from which the soil is apparently derived. Laterite concretions, on the other hand, are shown to contain large amounts of iron as  $Fe_2O_3$  derived from rocks of a ferruginous nature.

The author expresses the opinion that a study of the constitution and origin of concretionary deposits of soils may be expected to aid in the interpretation of the weathering processes of a given region.

**Chemical and physical nature of red soils, E. BLANCK** (*Jour. Landw.*, 60 (1912), No. 1, pp. 59-73; *abs. in Chem. Abs.*, 6 (1912), No. 14, p. 1948; *Jour. Chem. Soc. [London]*, 102 (1912), No. 595, II, pp. 482, 483).—A chemical study of red laterite soils of the Mediterranean region and of the red soils of more northern regions, around Münzenberg, showed no essential differences in the content, solubility, or form of combination of the iron and aluminum. It was found, however, that the surface area (as determined by the modified Mitscherlich method) in proportion to the amount of ferric oxid and soluble alumina was greater in the Mediterranean red soils than in the Münzenberg soils. This is thought to be due partly to the colloidal condition of the iron oxid.

**The origin of sea marshes, SCHÜRTE** (*Arb. Deut. Landw. Gesell.*, 1911, No. 178, pp. 49, figs. 19).—This is an account of observations on the formation, causes of productiveness, fauna and flora, and agricultural value of the North Sea marshes.

**Analyses of soils of German Southwest Africa, C. GRIMME** (*Arb. Deut. Landw. Gesell.*, 1911, No. 197, pp. 128-135).—In connection with a study of the grazing possibilities in German Southwest Africa, the author made physical and chemical analyses of samples of soil from seven different districts of the region. Taking one-tenth per cent as normal, the results showed that out of 24 soils, 11 lacked nitrogen, 8 phosphoric acid, and 1 potash. Two soils were deficient in lime.

**Pumice soils, B. C. ASTON** (*Jour. New Zeal. Dept. Agr.*, 4 (1912), No. 5, pp. 374-377, fig. 1).—This article describes the physical characteristics and crop adaptation of pumice soils of the North Island, New Zealand, central volcanic plateau. The soils are derived from eruptive rocks which have undergone very little alteration by weathering processes. It is stated that although classified as coarse sands, these soils contain "a less amount of silica (which is in the combined state) and a larger amount of plant food than the majority of sands."

Methods of improvement depend largely on increasing the store of humus and applications of phosphatic fertilizers.

**Rock and soil in relation to plant nutrition with special reference to the cementing material of sandstone, E. BLANCK** (*Landw. Vers. Stat.*, 77

(1912), No. 3-4, pp. 129-216, pl. 1; *abs. in Ztschr. Angew. Chem.*, 25 (1912), No. 40, p. 2085).—The author reviews the literature bearing on this subject and reports pot experiments with oats and peas grown on sand and on freshly crushed sandstone of different kinds. It was found that the cementing material of the sandstones contained readily available plant food, which is largely lost during weathering, as illustrated by the results with sand, which is the extreme product of the weathering process.

**Acid excretion of roots and the solubility of plant food constituents of the soil in water solutions of carbon dioxide**, T. PFEIFFER and E. BLANCK (*Landw. Vers. Stat.*, 77 (1912), No. 3-4, pp. 217-268).—The authors critically review the work of other investigators on this subject and report the results of experiments on the assimilation of phosphoric acid from monocalcium phosphate and different phosphorites by oats, lupines, and peas, grown in pots, the soil in which was kept charged with carbon dioxide. The carbon dioxide was conducted under pressure into the soil through the ventilation tubes of the pots. The soil was completely saturated in this way three times a week. The water content of the soil was maintained at 10 per cent during the experiment.

The results showed that addition of carbon dioxide gave favorable results only with the easily soluble phosphates. The phosphorites required stronger acid solvents to render them available to plants. It was also observed that the assimilation of phosphoric acid was greater for the legumes than for oats. The addition of carbon dioxide did not offset this difference.

The general conclusion, therefore, is that the assimilative power of plant roots is not dependent alone upon the carbon dioxide given off, but that other organic acids play an important rôle.

**The action of different solvents on the plant-food constituents of the soil**, O. ENGELS (*Landw. Vers. Stat.*, 77 (1912), No. 3-4, pp. 269-304; *abs. in Chem. Abs.*, 6 (1912), No. 14, pp. 1948, 1949).—The author reviews previous investigations on the subject by others and reports results of studies of the relative solubility of phosphoric acid, potash, and lime of soils in 10 per cent hydrochloric acid, 2 per cent citric acid, water solutions of carbon dioxide, and distilled water, using four different soil types ranging from light sands to heavy clays. In order to determine the solubility of the plant-food constituents in the original, as distinguished from the absorbed state, the experiments were made (1) on the untreated soil and (2) after treatment with 18 per cent solutions of superphosphate and potassium sulphate.

It was found that, although the solubility of the plant-food constituents varied, there was a uniformity in the action of the solvents. The absorption of phosphoric acid and of potash also varied for the different soils, being higher for the heavy clay soils, which contained also the higher lime, iron oxide, and alumina contents, and decreasing for loess loam and sandy soils in the order named. The solubility of the absorbed phosphoric acid was much higher for the lighter soils with low lime content. This was also true for the solubility of the potash, although the difference in solubility was not so pronounced.

The solubility of phosphoric acid and potash in the water solutions of carbon dioxide was substantially greater than that in water, being twice as great in the case of phosphoric acid and increasing in the case of potash in sandy soil from 34.08 to 55.08 per cent. The difference was less marked in the heavier soils.

The 2 per cent solution of citric acid dissolved substantially all the absorbed phosphoric acid and 90 per cent of the potash in case of sandy soils, whereas with the three heavier soils considerable amounts of the phosphoric acid and about one-third of the potash remained fixed in the soil.

The author, therefore, concludes that a 2 per cent solution of citric acid is the most reliable solvent for determining the readily soluble mineral constituents of the soil in that, unlike the other solvents used, it gives equally reliable results for both phosphoric acid and potash.

Determinations of the value of plant food constituents in soils and fertilizers as dependent upon solubility, J. G. MASCHHAUPT and L. R. SINNIGÉ (*Verlag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], 1912, No. 11, pp. 19-73*).—The author gives a critical review of investigations by Mitscherlich on this subject (E. S. R., 19, pp. 110, 911), and reports the results of his own studies of the solubility of different phosphates in saturated water solutions of carbon dioxide and in citric acid (2 per cent) by single and repeated extraction.

The results showed that continued extraction with fresh quantities of the solvents was a more reliable method of determining the solubility of the phosphates and their fertilizing value than a single extraction. The water solution of carbon dioxide is preferred to citric acid on account of the fact that it is the most important, although not the only, solvent at the disposal of the soil and the plant roots, although the contention of Mitscherlich, that the action of carbon dioxide solutions is similar to that of the roots in physiological processes of plant growth, is not accepted.

Remarks on absorptive saturated and unsaturated soils, A. RINDELL (*Separate from Pochvorédânie (Pédologie), 1912, No. 1, pp. 11*).—This is a brief critical discussion of the views of Ramann and of Gedroits (E. S. R., 26, p. 30).

The author holds that the classification of soils as absorptive saturated and unsaturated is too indefinite to be of value, except as denoting whether a soil is rich or poor in absorptive combined bases. The judging of the absorptive properties of soils by their chemical behavior toward neutral salt solutions is also of no value without a knowledge of the kind of bases absorbed.

The relation of evaporation to the water content of the soil at the time of wilting, W. H. BROWN (*Plant World, 15 (1912), No. 6, pp. 121-134*).—Experiments to determine the relation between the evaporating power of the air and the percentage of water in the soil at the time of wilting of plants of *Martynia louisiana*, *Physalis angulata*, *Tropaeolum majus*, and *Vicia faba*, are reported.

The plants were grown "first in the open, exposed to the direct rays of the sun; second, under a lath shelter; third, in a room within a thick-walled adobe house; fourth, in a glass chamber in the same room, the air in this chamber being kept nearly saturated with moisture." The soil used was a mixture of equal parts, by dry volume, of clay-loam and sand with a water-holding capacity of 31.4 per cent of the weight of dry soil.

The results of these studies showed that the percentage of soil moisture at the time of wilting of the plants grown under the same conditions and in the same soil varied "with the rate of evaporation at the time of wilting, providing, however that, in the case of altered conditions, the plant is not allowed time enough under the new evaporation rate to become physiologically altered.

"This residual moisture content of the soil at the time of wilting varies according to the atmospheric conditions under which the plant has been grown and appears to be increased by excessive soil temperatures."

The moisture content of the soil at the time of wilting varied among the different plants "within but comparatively narrow limits for any given evaporating power of the air during the hour preceding wilting."

Data and observations on the salt content of drainage waters of the polders of North Netherlands, A. D. BERKHOUT (*Cultura, 24 (1912), No. 286, pp. 227-232, fig. 1*).—Determinations were made of the sodium-chloride content of

the drainage waters and polder soils surrounding Westerkogge, Netherlands, with a view of ascertaining whether sufficient quantities were present to injure vegetation. The salt content in the drainage water varied from 0.1 to 10.82 gm. per liter, that in the surface soil from 0.005 to 0.051 per cent, and that in the subsoil from 0.005 to 0.140 per cent. It is not believed that these quantities were injurious to the vegetation.

The influence on soil temperature of additions of sand to moor soils, H. VON FEILITZEN (*Internat. Mitt. Bodenk.*, 2 (1912), No. 1, pp. 45-52, figs. 2).—Tests of the influence on the temperature of moor soils of a sand layer of 1,500 cubic meters per hectare (about 794 cu. yds. per acre), as compared with mixing sand with the soil at the rate of 500 cubic meters per hectare, are reported. The results show that the temperature was increased much more markedly by the layer of sand than by mixing. Mixing the sand with the soil increased the temperature early in spring, but thereafter had no effect.

Soil bacteriology in agriculture, C. B. LIPMAN (*Cal. Cult.*, 38 (1912), No. 26, pp. 771-773, 779).—This article summarizes concisely and indicates the practical bearing of what investigation has shown to be the relations of bacterial activity in the soil to aeration, water, temperature, humus, manures and fertilizers, sulphur and iron, carbon dioxide, soil inoculation, and sterilization.

Relation of soil bacteria to evaporation, C. HOFFMANN (*Wisconsin Sta. Research Bul.* 23, pp. 183-215, fig. 1).—Preliminary investigations having shown that Stigell's method of studying the relation of bacterial activity to evaporation in the soil (E. S. R., 20, p. 620) gave contradictory results, the author adopted the following method of procedure: "

Five hundred or 600 gm. of air-dried soil, passed through a 12-mesh sieve, was placed in circular dishes either 19.1 or 21 cm. in diameter, making, when uniformly packed and leveled, a soil layer 2.8 cm. deep in the larger dishes and 3.2 cm. in the smaller dishes. "To each of the plates were then added by means of a 50 cc. pipette, 150 to 300 cc. of distilled water depending upon the nature and amount of soil employed, the water being applied either pure or modified as indicated under the individual experiments. It was planned to have approximately 30 per cent of moisture present initially in all experiments, thus affording ample moisture for vigorous bacterial multiplication. . . . In all cases the total initial weight was recorded and subsequent weighings were then made at more or less frequent intervals to determine the rate of evaporation. . . . The results of the individual dishes of each set were then added and the average taken to indicate the loss due to evaporation occurring from period to period."

A study was made by this method of the evaporation from untreated soil and from that sterilized with mercuric chlorid. Although the results were variable with individual plates, they were uniformly and considerably higher in the inoculated plates than in the sterile plates.

"One finds the maximum interval variation between sterile and normal sets in the greenhouse and the field clay soils, and the least variation with the sandy soil. On total variations the greenhouse soil exceeds all others, showing as a maximum 19.02 gm. difference in favor of the inoculated set. It is interesting to note that in all cases the rate of evaporation was more rapid in the inoculated set than in the sterile set."

A study of the relation of bacterial multiplication to evaporation apparently indicated that the bacterial activities were responsible for the increased rate of evaporation in the normal or inoculated series. Remoistening the partly dried plates increased the rate of evaporation in the inoculated soils over that initially observed. The addition of 1 per cent blood meal increased evaporation from inoculated soil over sterile soil, but addition of 1 per cent barnyard manure decreased the difference.

"The results here obtained seemingly contradict all previous work, for in the series receiving manurial additions the sterile plates exceed the normal or inoculated ones in the rate of evaporation. This is true in both cases where manure was added. It is noteworthy, however, that the untreated series showed an acceleration in the rate of evaporation in the inoculated plates which harmonizes with the results of previous work."

Addition of 2 per cent meal produced less effect than 1 per cent and addition of 2 per cent manure reduced the evaporation due to bacterial activity.

By means of a series of percolator tests there was found to be increased capillary rise of moisture in the inoculated soil. It was also shown that evaporation was increased by the gas formation due to bacterial activity in the inoculated soil.

The results of tests with soils inoculated with pure cultures of *Azotobacter* and *Bacillus subtilis* confirmed those with soils containing mixed cultures.

The general conclusion is "that the soil bacteria and their activities are factors which must be considered when discussing the movement of soil water; not so much because of the cells themselves as because of the by-products which they form and the subsequent influence of the same upon such factors as surface tension, capillarity, viscosity, etc., of the soil moisture. The biological feature of the soil apparently forms an important contributory factor in determining the movement of soil water."

The nitrogen cycle in the soil, E. J. RUSSELL (*Chem. World*, 1 (1912), No. 6, pp. 185-187, fig. 1).—In this article the position is taken that most of the reactions of the nitrogen cycle of the soil are bacterial.

Studies in soil bacteriology.—V, The nitrifying and ammonifying powers of North Carolina soils, F. L. STEVENS, W. A. WINTERS, ET AL. (*Centbl. Bakt. [etc.]*, 2. Abt., 34 (1912), No. 8-9, pp. 187-203, figs. 13).—In continuation of previous studies (E. S. R., 23, p. 721), tests were made of the nitrifying and ammonifying power of samples of typical soils from different parts of the State. An attempt is made to correlate the results with the crop-producing power of the soils.

About 42 per cent of the soils showed no nitrification. It was as a rule more active in soils which had grown legumes or had been manured than on soils not so treated. No positive relation between nitrification and productiveness was established. Ammonification was very variable.

A summary of investigations on nitrogen fixation of *Azotobacter chroococcum*, G. RÖSING (*Centbl. Bakt. [etc.]*, 2. Abt., 33 (1912), No. 25, pp. 618-623).—The work of T. Remy and the author on this subject is summarized.

The results of the investigations, which have been in large part reported and noted from time to time, show that lime and magnesia increased the amount of nitrogen fixed in Beijerinck's mannit solution by *Azotobacter*. Free acid, which prevented any marked bacterial development, was neutralized by lime or magnesia, thus enabling the organisms to utilize the carbohydrates added as sources of energy. Mannit, sucrose, and dextrose in connection with mannit, were especially favorable as such sources of energy. The gain in nitrogen during a period of 6 weeks from additions of sucrose (2 per cent) was 103 mg. per kilogram of soil. Tests showed that the nitrogen thus fixed in the soil was a useful source of supply of this constituent to the higher plants. About 32 per cent of nitrogen fixed in the soil was assimilated.

Humus acids increased the fixation of nitrogen in nutritive solutions, the maximum amount being produced for 0.1 gm. of humus acid per gram of Beijerinck's mannit solution. The active constituent of the humus acid was found to be iron. A solution of 1 gm. iron chlorid, 10 gm. cane sugar, and 0.8 gm. of sodium per liter was especially beneficial to the bacterial activity.

The amount of nitrogen fixed per gram of Beijerinck's mannit solution was increased from 2.23 mg. to 10.3 mg. by addition of the iron solution. The form of the iron was also found to have an important influence, there being a much greater fixation of nitrogen with applications of iron in form of Thomas phosphate and of iron silicate, than with equal applications in the form of other compounds of organic as well as of inorganic character. The beneficial effect increased with the larger amounts of iron.

The author states that although the exact nature of the action of the iron has not been definitely determined, it would seem that the main process is one in which the iron acts as a catalytic agent, changing the nitrogen of the air to nitrite. In this form it is taken up by the bacteria, whereupon new nitrite is formed, the process going on continually.

**The influence of stall manure upon the bacterial flora of the soil, J. C. TEMPLE** (*Centbl. Bakt. [etc.]*, 2. Abt., 34 (1912), No. 8-9, pp. 204-223).—These investigations have already been noted from another source (E. S. R., 26, p. 31).

**Earthworms and the fertility of the soil, C. BEAUGÉ** (*Jour. Agr. Prat.*, n. ser., 23 (1912), No. 16, pp. 506, 507).—Investigations carried on by the British Government in the valley of the White Nile in the Sudan indicate that the great fertility of the soil of this valley is due in large part to the work of earthworms. Observations are recorded from which it is estimated that the castings of earthworms on these soils during the 6 months of the most active growing season of the year amounts to 239,580 lbs. per acre. The author reports similar observations in Upper Egypt from which it is estimated that the castings in this region amount to 58,785 lbs. during the 6 months.

[**Maintenance of soil fertility in China, Korea, and Japan**], F. H. KING (In *Farmers of Forty Centuries*, Madison, Wis., 1911, pp. IX+441, pl. 1, figs. 248).—The results are here given of a study of the agricultural methods and practices of these countries, particularly of the intensive methods of soil management, developed by a people who with almost no fertilizer resources except those of the farm, the home, and the town, have maintained the productivity of fields for more than 3,000 years, supporting a population of nearly 500,000,000 people upon an area smaller than the improved farm lands of the United States. The secret of this success is shown to be utilization of the products of the soil so that there shall be no waste of fertility.

"Almost every foot of land is made to contribute material for food, fuel, or fabric. Everything which can be made edible serves as food for man or domestic animals. Whatever can not be eaten or worn is used for fuel. The wastes of the body, of fuel, and of fabric worn beyond other use are taken back to the field; before doing so they are housed against waste from weather, compounded with intelligence and forethought, and patiently labored with through one, three, or even six months, to bring them into the most efficient form to serve as manure for the soil or as feed for the crop."

In Japan there were in 1907 "some 5,814,362 households of farmers tilling 15,201,969 acres and feeding 3,522,877 additional households, or 51,742,398 people. This is an average of 3.4 people to the acre of cultivated land, each farmer's household tilling an average of 2.6 acres. The lands yet to be reclaimed are being put under cultivation rapidly, the amount improved in 1907 being 64,448 acres. If the new lands to be reclaimed can be made as productive as those now in use there should be opportunity for an increase in population to the extent of about 35,000,000 without changing the present ratio of 3.4 people to the acre of cultivated land."

In the author's opinion, the agriculture of the newer nations would be greatly benefited by a careful consideration of the intensive methods of these countries.

"When we reflect upon the depleted fertility of our own older farm lands, comparatively few of which have seen a century's service, and upon the enormous quantity of mineral fertilizers which are being applied annually to them in order to secure paying yields, it becomes evident that the time is here when profound consideration should be given to the practices the Mongolian race has maintained through many centuries, which permit it to be said of China that one-sixth of an acre of good land is ample for the maintenance of one person, and which are feeding an average of three people per acre of farm land in the three southernmost of the four main islands of Japan."

How may fertilizer experiments be improved? A. W. K. DE JONG (*Tcysmannia*, 22 (1911), Nos. 6, pp. 349-362; 7, pp. 425-441; 9-10, pp. 562-574; 11, pp. 675-701, pl. 1, figs. 4; 23 (1912), Nos. 3, pp. 135-175, figs. 11; 5, pp. 297-307).—This is mainly a summary of the more important information contained in previous articles on the same subject by Wagner, A. Mayer, Wohltmann, Drechsler, Fleischer, Liebscher, Dafert, Mitscherlich, Holtsmark and Larsen, H. M. Gmelin, Middleton, Wood and Stratton, and Mercer and Hall (E. S. R., 15, p. 130; 16, p. 658; 17, p. 903; 18, p. 436; 19, p. 531; 22, p. 223; 24, p. 633; 25, p. 825; 26, p. 732). The article is a very complete review of recommendations which have been made by various investigators for the improvement of the accuracy of field experiments with fertilizers.

On the discrepancy between the results obtained by experiments in manuring, etc., in pots and in the field, L. COHEN (*Jour. and Proc. Roy. Soc. N. S. Wales*, 43 (1909), pt. 2, pp. 117-122; *abs. in Chem. Abs.*, 6 (1912), No. 10, p. 1332).—It is suggested that the discrepancies may be due to variations in concentration of the soil solution. "There is undoubted evidence that in ordinary soil of medium fertility the use of soluble fertilizers is without profit, in fact in certain cases positively detrimental, unless a correspondingly large amount of water is used on the growing crop, so as to bring the soil moisture below the maximum limit of concentration during its growth." The importance of exact studies along this line is pointed out.

Loss of fertilizer constituents in drainage water, A. W. BLAIR (*Proc. Fla. State Hort. Soc.*, 24 (1911), pp. 105-111, pl. 1, fig. 1).—The tanks installed at the Florida Station for the study of this subject (E. S. R., 25, p. 117) are described and some of the preliminary results obtained with them are reported.

Experiments with sodium nitrate, calcium nitrate, and calcium cyanamid on moor soils, A. RINDELL (*Meddel. Finska Mosskulturför. Försöksv.*, 3 (1911), pp. 22; *abs. in Zentbl. Agr. Chem.*, 41 (1912), No. 5, pp. 317-321).—In these experiments, on Finnish moor soils in need of nitrogen, barnyard manure was found to be more effective than sodium nitrate. The relative efficiency of sodium nitrate, calcium nitrate, and calcium carbonate varied with the amount of the application and the character of the soil.

The present status of the artificial nitrogen fertilizer industry, F. W. DAFERT (*Österr. Chem. Ztg.*, 15 (1912), No. 7, pp. 86-89).—The present status of the manufacture of ammonium sulphate, nitric acid, lime nitrogen, nitrids, and the like, is briefly reviewed.

The nitrate of soda industry of Chile, B. DIAZ-OSSA (*Rev. Gén. Sci.*, 23 (1912), No. 10, pp. 389-396, figs. 8; *Sci. Amer. Sup.*, 74 (1912), No. 1910, pp. 82, 83, figs. 8).—This article, by the professor of nitrate of soda technology of the University of Chile, discusses briefly the history of development of the industry, the location and character of the deposits, and methods of exploitation and purification of the nitrate.

The author is of the opinion that there is now enough nitrate in sight to supply the actual demand for a century. The complex character of the salts is pointed out. They contain besides sodium nitrate, chlorid, and sulphate, potas-

sium chlorid, calcium sulphate and nitrate, magnesium chlorid, sulphate, and nitrate, sodium iodate, sodium nitrosulphate (darapskite), calcium iodate (lautarite), and calcium iodochromate (dietzeite). The soils of the region are stated to be highly radioactive.

New methods in the ammonia industry, V. HÖBLING (*Osterr. Chem. Ztg.*, 15 (1912), No. 9, pp. 114-118, figs. 5; *Engrais*, 27 (1912), No. 41, pp. 1133-1137).—Recently proposed methods of manufacturing ammonia are briefly described.

[Nitrogenous fertilizers derived from the air] (9. *Cong. Internat. Agr. Madrid*, 1911, pp. 762-844).—The fertilizer section of the Ninth International Congress of Agriculture at Madrid was devoted exclusively to the consideration of papers on nitrogenous fertilizers obtained from the air as follows: Study and Application of New Fertilizers Prepared from the Nitrogen of the Air, by E. Noriega Abascal; Nitrogenous Fertilizers and Calcium Cyanamid, by L. Rebello da Silva; Study of the New Fertilizers Prepared from the Nitrogen of the Air, by C. Schreiber; Importance of Synthetic Nitrogenous Fertilizers in Agriculture, by M. Weitz; Nitrogenous Fertilizers Derived from the Air, by J. Úbeda Correal; and Cyanamid, by C. Pluvinage.

These papers set forth quite fully the present status of the manufacture and use of nitrogenous fertilizers derived from the air from the agricultural standpoint.

The conclusions of the congress were generally favorable to the use of these fertilizers under conditions and precautions which are carefully defined.

The toxic action of organic compounds as modified by fertilizer salts, O. SCHREINER and J. J. SKINNER (*Bot. Gaz.*, 54 (1912), No. 1, pp. 31-48, figs. 5; *Science*, n. ser., 33 (1911), No. 844, p. 340; *Chem. Abs.*, 6 (1912), No. 9, p. 1196).—"The action of fertilizer salts in restraining the harmful influence of certain organic compounds was studied, as well as the effect of the compounds on absorption. The culture solutions comprised all possible ratios of the three principal fertilizer elements, phosphate, nitrate, and potassium, varying in 10 per cent stages. . . .

"The cumarin depressed potash and nitrate removal from nutrient solution more than phosphate; the quinone, on the other hand, depressed phosphate and nitrate more than potash; the effect of vanillin was not determined in this regard. It is interesting to mention that dihydroxystearic acid, which, as previously reported, appears to act much as vanillin did, depressed phosphate and potash more than nitrate. In this respect again the influence of the various harmful substances was different.

"The conclusion is drawn that different toxic substances produce definite effects in their action on plants and that the effects are modified differently by the different fertilizer salts."

See also a previous note (*E. S. R.*, 26, p. 224).

The effect of the "wet process" on the availability of low-grade nitrogenous materials, B. L. HARTWELL and F. R. PEMBER (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 6, pp. 441-443).—An abstract of this paper has been noted (*E. S. R.*, 26, p. 725).

Relation of active potash to pot experiments, G. S. FRAPS (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 7, pp. 525, 526).—This is a summary of experiments reported in full in Bulletin 145 of the Texas Station (*E. S. R.*, 27, p. 323).

Mica as a source of potash for plants, E. BLANCK (*Jour. Landw.*, 60 (1912), No. 2, pp. 97-110; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 597, II, p. 677; *Ztschr. Angew. Chem.*, 25 (1912), No. 40, p. 2085).—Pot experiments in which muscovite and biotite were used as sources of potash supply to oats are reported, the results showing that the potash of muscovite was much less readily available than that of biotite, but was assimilated by the plant much more

readily than the potash of feldspar. From 10.37 to 14.67 per cent of the potash of biotite was assimilated, as compared with from 1.66 to 2.86 per cent of the potash of the muscovite.

**Preparation of superphosphate with sulphur dioxide and chlorine, Q. SERTINI** (*Indus. Chim.*, 12 (1912), pp. 49-53; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 6, p. 293).—Experiments are reported which showed that it is possible to prepare superphosphate by the combined action of sulphur dioxide and chlorine on crude mineral phosphate according to the following equation:

**Guano supply of French Somaliland, W. A. SCHULZ** (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 162, p. 189).—It is stated that the abundant supplies of guano on the numerous small islands along the coast of French and Italian possessions in the Red Sea are beginning to be exploited, recent shipments having been made to Antwerp and Suez through the port of Jibuti. The guano is stated to be of high quality.

**Fertilizer from city refuse** (*Municipal Jour. and Engin.*, 30 (1911), Nos. 19, p. 678, figs. 2; 26, p. 918).—A machine which has been in operation at Southwark, England, for grinding garbage and preparing a fertilizer suitable for use on stiff clay soils is described.

**The utilization of sewage sludge** (*Engin. Rec.*, 65 (1912), No. 26, pp. 701, 702).—The practicability of the use of sewage sludge as fertilizer is questioned, as is also the economy of extracting grease from the material, although the latter process increases the value of the sludge for fertilizing purposes. The authorities cited are G. W. Fuller (*E. S. R.*, 27, p. 212) and W. Naylor (*E. S. R.*, 27, p. 318).

**Annual report on fertilizers August 1, 1911, B. B. ROSS** (*Ann. Rpt. Ala. Dept. Agr. and Indus.*, 1911, pp. 163-316).—Analyses and valuations of fertilizers inspected in Alabama are reported, with the text of the state fertilizer laws and a brief discussion of the nature and use of fertilizers.

**Analyses of commercial fertilizers, M. A. SCOVELL and H. E. CURTIS** (*Kentucky Sta. Bul.* 158, pp. 197-328).—This bulletin reports analyses and valuations of fertilizers inspected by the Kentucky Station during 1911. The results show "that in most cases the samples analyzed have come fully up to the guaranty or, where there is a slight deficiency in one ingredient, it has been made up by an excess in one or both of the other ingredients."

**Russian fertilizer situation** (*Amer. Fert.*, 37 (1912), No. 1, pp. 38, 39).—Figures are given which show that the amount of fertilizer used in Russia nearly trebled in the 5 years 1907 to 1911, being in the latter year 360,000 short tons. The use of fertilizers in the Empire is, however, still comparatively small. The fertilizers used are practically all imported, although considerable quantities of bones, fish waste, slaughterhouse by-products, and similar materials are exported. Large deposits of phosphates are available.

## AGRICULTURAL BOTANY.

**Chemical effects of radiant energy in plant processes, H. A. SPOEHR** (*Carnegie Inst. Washington Year Book*, 10 (1911), p. 65).—Experiments in photochemical reactions supposedly similar to those occurring in plants have been carried out.

It was found that aqueous solutions of potassium and calcium nitrates are reduced by means of ultraviolet light, sunlight, and diffused light to the corresponding nitrites and ammonia, with the liberation of oxygen and the production of alkalinity in the solution. It is claimed that Schimper has shown that the disappearance of nitrates in the leaf takes place in the sunlight. If, there-

fore, the above reaction takes place in the leaf, not only would the proper conditions for carbohydrate synthesis be established, but the nitrogen would also be produced in the best form and the most available place for protein synthesis.

The rôle of organic acids in the plant leaf and the relation of these substances to protein synthesis are under investigation. It has been found that the hydroxy-acids, under the influence of ultraviolet light, are decomposed, yielding carbon dioxide and aldehyde-like substances. These are believed to be necessary in the further synthesis of compounds of importance to the organisms.

**Rhythm in plant development**, G. KLEES (*Sitzber. Heidelb. Akad. Wiss., Math. Naturw. Kl., 2 B (1911), Abhandl. 23, pp. 84; abs. in Bot. Centbl., 119 (1912), No. 17, p. 426*).—Continuing previous work by the author (*E. S. R., 24, p. 141*), an account is given of studies made on 40 living European plants taken from their native environment to Java and there observed under control conditions, in order to ascertain whether or not the tendency to vary between periods of alternate growth and rest is inherent or dependent upon external conditions.

It was found that the most of these plants showed continued growth in the new situation during the time when in Europe they would be at rest, but that a somewhat marked resting period could be induced by lowering such life conditions as temperature, moisture, nutrition, etc. This and further facts observed led the investigator to advise caution in accepting the theory that an inner periodicity exists, and to favor the view that periodicity depends very largely upon climatic and nutritive conditions.

A bibliography is appended.

**Transpiration in succulent plants**, Miss E. M. DELF (*Ann. Bot. [London], 26 (1912), No. 102, pp. 409-442, fig. 1*).—The author has made a study of transpiration in relation to the structure and habitat of succulent plants, particular attention being given to the transpiring surface and water storing and conducting systems.

It was found that the chief structural peculiarities of succulent plants are connected with the transpiring surface and the storage of water. Summing up the characteristics of the transpiring surface, the author found that succulent plants show a varying amount of reduction in the leaf surface, and that this may or may not be accompanied by arrangements which tend to diminish transpiration. Most succulent plants are characterized by the possession of definite aqueous tissue; others have a great development of mesophyll in the leaves, and then the innermost layers tend to function as storage cells for water.

The author states that the peculiarities of succulent plants must be regarded as adaptations to environment of real importance to the plant. They may be produced during the lifetime of the individual, as in the development of additional mesophyll or storage tissue in a facultative halophyte, or they may appear as permanent characteristics, as in the case of plants that are found exclusively in saline situations.

**The water relations of halophytes and sclerophylls**, F. E. LLOYD (*Carnegie Inst. Washington Year Book, 10 (1911), pp. 61, 62*).—The author gives a brief summary of investigations to determine the absolute, relative, and cuticular transpiration of a number of beach plants and of trees and shrubs from neighboring slopes. A method was devised for observing the actual condition of stomata on living leaves, and from the investigations tentative conclusions were reached as follows:

“(1) Little variation in the actual amount of water in the leaves was observed, and the rate of loss was low in the cool air and high humidities of the Carmel region in which the work was performed.

"(2) The beach plants or halophytes showed a lively stomatal activity—a remarkable readiness to wilt and desiccate. In this particular such plants are widely different from the fleshy plants of the desert.

"(3) The osmotic pressures of the thick leaves of beach plants are equivalent to 0.2 to 1.3 potassium nitrate, or 7.5 to 48 atmospheres. The pressure in the roots is notably lower, as in other plants.

"(4) The amount of water vapor which any of these plants may absorb from the air is small and of little significance in the life of the plant."

The influence of methylene blue on the respiration of plants, W. PALLADIN, ELISE HÜBBENET, and MARIE KORSAKOW (*Biochem. Ztschr.*, 35 (1911), No. 1-2, pp. 1-17, fig. 1; *abs. in Jour. Chem. Soc. [London]*, 100 (1911), No. 588, II, pp. 919, 920; *Bot. Centbl.*, 119 (1912), No. 17, pp. 427, 428).—This contains investigations made by W. Palladin, partly in connection with others, on the respiration of living and killed plants (*E. S. R.*, 23, p. 629; 25, pp. 123, 411; 27, p. 426), the principal findings now reported being as follows:

With access of air the respiration with etiolated tips of *Vicia faba*, colored with methylene blue, is increased by from 65 to 107 per cent; while that of *Pisum sativum* is increased from 11 to 18 per cent. The action of quinin is, in general, similar to this; but, while the respiration of seeds of *V. faba* is increased by methylene blue, that of seeds of *P. sativum* is diminished. The differences observed are ascribed to the larger amounts of respiratory chromogen contained in the objects most affected, and to the alleged fact that, where little of such chromogen is present, quinin usually shows a poisonous action. Killing *V. faba* by means of cold stops the stimulating action of the methylene blue. The anaerobic respiration of stem tips of *V. faba* and *P. sativum*, stimulated with methylene blue, is progressively checked. It appears as if in absence of oxygen the cells are not able to protect themselves from the influence of the methylene blue, which then tends to act as a poison. Other differences between the action of the methylene blue on aerobic and anaerobic respiration are demonstrated. The ratio of anaerobic carbon dioxide separation to alcohol production is about 1:1 for colored seeds, while for the control seeds it is smaller. Disodium hydrogen phosphate paralyzes the injurious action of methylene blue on etiolated tips of *V. faba*.

The influence of methylene blue on the respiration of plants, ELISE HÜBBENET (*Trudy Imp. S. Peterb. Obshch. Estestvo. (Trav. Soc. Imp. Nat. St. Petersb.)*, 42 (1911), I, No. 7-8, pp. 279-292, 308, 309).—The substance of this article has been given in the above article.

The freezing of plants, H. MOLISCH (*Schr. Ver. Naturw. Kenntnisse Wien*, 51 (1910-11), pp. 141-176, figs. 7; *abs. in Bot. Centbl.*, 119 (1912), No. 16, pp. 404, 405).—An account is given of numerous freezing experiments with various higher and lower plants, with amœbæ, and with other objects.

Emphasis is laid on the extraction of cytoplasm in the freezing process, following which the protoplasm is seen to be shriveled into a shapeless mass or into a network with water outside or occupying the interstices. According to the author, any of 3 forms may result from freezing, depending upon whether ice forms inside the cell, outside the cytoplasm, or in both these situations. It is claimed as regards the survival of the plant it matters little as a rule whether it be thawed out quickly or slowly. The resistance offered by some plants to cold is thought to depend upon the constitution of the plasma.

A short bibliography is appended.

Some effects of severe frosts upon vegetation in a condition of active growth, F. K. BUTTERS and C. O. ROSENDAHL (*Minn. Bot. Studies*, 4 (1911), pt. 2, pp. 153-159, pl. 1).—This is a detailed account of investigations, a pre-

liminary notice of which has been given elsewhere (E. S. R., 25, p. 128), and summarized as follows:

"(1) Prolonged solid freezing will injure many plants and parts of plants which are not hurt by 2.5° (C.) of frost. (2) Mechanical damage from loss of turgidity and brittleness of frozen members is great. (3) Hard freezing is far more destructive to our native woody plants than to our herbaceous vegetation. (4) Woody plants recover from hard freezing very slowly and produce very abnormal growth for the season in which it occurs."

Chemical protection of plants against freezing, N. A. MAKSIMOV (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 13 (1912), No. 1, pp. 1-26).—This is in substance the same as a report previously noted (E. S. R., 27, p. 333). A more extended report with the more general conclusions reached is promised.

Germination of seed as affected by sulphuric acid treatment, H. H. LOVE and C. E. LEIGHTY (*New York Cornell Sta. Bul.* 312, pp. 293-336, figs. 9).—The results are given of a study of the effect of sulphuric acid to hasten the germination of hard leguminous seed. Concentrated acid, with a specific gravity of about 1.84, was used, and seeds of red, white, alsike, sweet, and Japan clover, alfalfa, several weeds, and cotton were subjected to the influence of the acid for various periods of time.

The authors found that increased germination was secured by treating all the seeds with concentrated sulphuric acid. The effect of the treatment was still apparent after the seed had been allowed to dry before germination. Many varieties of weed seeds commonly found in samples of clover or alfalfa seeds were killed by the acid treatment, while the germination of others was either benefited or not at all affected. Cotton seed was easily delinted upon treatment, and the germination increased and hastened.

The method of treatment for different quantities of seed is described and consists essentially of subjecting the seed to sulphuric acid for from 15 to 45 minutes at ordinary room temperature, after which the seed is thoroughly washed. It may or may not be allowed to dry before planting.

The influence of the seed upon the size of the fruit in *Staphylea*, II, J. A. HARRIS (*Bot. Gaz.*, 53 (1912), No. 5, pp. 396-414, fig. 1).—In continuation of work previously noted (E. S. R., 27, p. 231) new data were obtained by the author, the conclusions from which may, in the main, be summarized as follows:

There is a very substantial interdependence between the number of seeds and the fruit length of *Staphylea*, higher than that between the number per locule and length, and in large measure independent of the influence of the number of ovules. Mechanical stretching by pressure of adjacent seeds as a factor seems to be excluded. In general, the facts observed are thought to warrant the conclusion that the interdependence between the number of seeds and the length of fruit in *Staphylea* is a direct physiological one and that the two characters stand in some degree in the relationship to each other of cause and effect.

Some points in the morphology and physiology of fasciated seedlings, T. REED (*Ann. Bot. [London]*, 26 (1912), No. 102, pp. 389-402, figs. 9).—Investigations on the seedling plants of various species of Leguminosae were carried on to determine some of the facts relating to fasciation. The seeds were germinated in soil, and when the plumular shoots had developed about an inch or so the apical bud was cut away and the seedlings allowed to resume their growth.

Two types of seedlings were used, the hypogeal and the epigeal types, but fasciations were induced only in the former class. The hypocotyl of hypogeal seedlings was found to become fasciated as the result of adherence of a number of fasciated shoots. The food reserves in the two types of seedlings may be similar chemically, but the availability of the food differs. Hypogeal seedlings

are said to be remarkably dependent on their cotyledonary food reserves for their early development as contrasted with seedlings of the epigeal type.

The transformation of reserve substance in tubers of *Dahlia variabilis*, N. SCIACCA and G. ZERILLI (*Ann. R. Scuola Sup. Agr. Portici*, 2. ser., 9 (1909), Art. 4, pp. 1-23).—In the respiration of dahlia tubers it was found that they consumed as much as 2.47 per cent of their total weight in 70 days; also the ordinarily insoluble material of the tubers was sensibly drawn upon. Respiration, which is most active when the tubers have given up about 30 per cent of their contained water, is slowest when the tubers are in a rarified atmosphere. In this situation, moreover, the insoluble material appears to take no part in respiration. The noninulin contents remain sensibly constant. The substances given off appear mainly as respiration products.

As the time for budding approaches, the inulin begins to pass into the more soluble forms of inuloid and levulose. The mobilization of inulin occurs in all parts of the tuber, but more particularly in the central cylinder which corresponds to the course of the fibrovascular bundles and which is in more direct relation to the young shoots. It appears from the experiments that the gradual hydrolyzing of the inulin is accompanied by a current of mobilization, the reserve material being transferred as it becomes soluble from the periphery toward the center.

Displacement by water of nutritive substances in plants, G. ANDRÉ (*Compt. Rend. Acad. Sci. [Paris]*, 152 (1911), No. 26, pp. 1857-1860; 153 (1911), Nos. 24, pp. 1234-1236; 26, pp. 1497-1500; 154 (1912), No. 17, pp. 1103-1105).—Continuing previous work (E. S. R., 25, p. 432), the author gives in a series of notes the detailed results obtained from a study of the distribution and diffusion of certain soluble substances in vegetable organs, also from his studies of the displacement of such substances by water in certain plants.

The significance of protein assimilation in the life processes of plants, F. EHRLICH (*Samml. Chem. u. Chem. Tech. Vorträge*, 17 (1912), pp. 297-310).—A brief discussion is given of the progress of research and of the present state of knowledge in this connection.

The building of protein by yeasts and mold fungi, F. EHRLICH (*Biochem. Ztschr.*, 36 (1911), No. 5-6, pp. 477-497; *abs. in Mycol. Centbl.*, 1 (1912), No. 2, pp. 52, 53).—A preliminary report is made on a series of investigations with *Willia anomala* and several mildew fungi.

It is stated that *W. anomala* is able to utilize besides sugar a number of relatively very simple organic substances, such as glycerin, lactic acid, and methyl, ethyl, and amyl alcohols as sources of carbon and energy in order to form its protein from amino acids; also that tyrosol is formed from tyrosin as from sugar during the growth of yeast in the culture medium. The author concludes that tyrosin in the presence of other carbon sources experiences no such thoroughgoing utilization as when the yeast in question ferments sugar.

In the culture with methyl alcohol, formic acid appears; in that with ethyl alcohol, acetic acid; and in that with amyl alcohol, valeric acid is formed. It appears as if strongly oxidizing enzymes present in *W. anomala* enable this yeast to utilize substances like alcohols, etc., as carbon supply and energy source. Such enzymes appear to be absent from the culture yeasts. *Oidium lactis*, *Rhizopus nigricans*, and other mildew fungi are able, like the "wild yeast," to employ glycerin, lactic acid, and ethyl alcohol for building protein from amino acid solutions.

Carbon assimilation by plants as affected by organic acids and their potassium salts, RAVIN (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 17, pp. 1100-1103).—From studies made on *Raphanus sativus* the author reports that malic, tartaric, citric, succinic, and oxalic acids, the organic acids most com-

monly met with in green plants, as well as their potassium salts, are absorbed by the root system of the radish and are assimilated; also that these acids are more nutritive than their acid potassium salts, and that these salts exceed in this respect the corresponding neutral salts.

The formation of saccharose in sugar beets, F. STROHMER, H. BRIEM, and O. FALLADA (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 40 (1911), No. 6, pp. 857-866).—The authors investigated sugar beets at the time of flowering and on ripening of seeds in regard to sugar content, etc., reaching the conclusion that sugar beets of the second year's growth are able to form sugar for storing purposes in their assimilating organs, not only in the stems but also in the roots.

A bibliography is appended.

The rôle of catalase in plants. W. ZALESKI and ANNA ROSENBERG (*Biochem. Ztschr.*, 33 (1911), No. 1-3, pp. 1-15; *abs. in Bot. Centbl.*, 119 (1912), No. 17, p. 431).—The authors report, as the result of their investigations, that the activity of catalase is considerably weakened by its extraction with ether or with ethyl or methyl alcohols, also in varying degrees by use of several other substances named. They seem to hold to the view that a relation exists between the activity of catalase and that of the oxidation process.

Comparison of the total nitrogen and nitric nitrogen in parasitic and saprophytic plants. L. LUTZ (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 19, pp. 1247-1249; *Bul. Soc. Bot. France*, 59 (1912), No. 4-5, pp. 370-373).—Studies were made of a number of phanerogamic absolute parasites, hemiparasites, and saprophytes with and without chlorophyll to determine the nitric nitrogen and total nitrogen which they contain.

As a result of the studies the author claims that absolute parasites, particularly those containing chlorophyll, are in general poorer in total nitrogen than the hemiparasites whose roots are in soil from which they can obtain nutritive material. The differences in nitric nitrogen are less marked. In general, plants containing chlorophyll are lower in nitric nitrogen as the percentage of total nitrogen increases, while with plants not containing chlorophyll the contrary was observed. The author claims that the figures presented indicate the important action of chlorophyll on the accumulation and assimilation of nitrogen by parasitic plants.

The relation of some fungi to organic acids, R. O. HERZOG, O. RIPKE, and O. SALADIN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 73 (1911), No. 3-4, pp. 284-307, figs. 3; *abs. in Jour. Chem. Soc. [London]*, 100 (1911), No. 588, II, p. 915).—In a series of papers by these authors accounts are given of the behavior of a number of mold fungi as affected by various organic acids. The fungi were cultivated in Ushinsky's nutrient medium, to which the different acids were added in amounts varying from 0.5 to 3 per cent.

When the molds were grown in these solutions for 6 weeks, they caused from 30 to 95 per cent of the acid to disappear, the different species of fungi transforming the acids in different amounts. Mycelium killed with acetone and ether and kept under water through which air was passed developed more carbon dioxid in the presence of acids, the acids being used up in the process.

In the second paper experiments with *Mycoderma cecrisiæ* are reported. This fungus killed by acetone and kept in solution of acetic or lactic acids caused a disappearance of the acid, which was not oxidized. Mandelic acid behaved in a similar manner, being chemically changed. Living fungi gave similar results with acids.

In the last paper the effect of amino acids on *Penicillium glaucum* is described, in which it is shown that the addition of leucin to a culture of the mycelium of the fungus caused a definite increase in the daily production of

carbon dioxid. The increase amounted to considerably more than could be accounted for by the leucin that had disappeared.

**Studies on iron-storing Hyphomycetes,** R. LIESKE (*Jahrb. Wiss. Bot. [Pringsheim]*, 50 (1911), No. 3, pp. 328-354, figs. 3; *abs. in Mycol. Centbl.*, 1 (1912), No. 1, p. 20).—The author was led by numerous observations on the rapid growth of certain fungi and bacteria in iron solutions to undertake a study of certain forms, in particular of one closely allied morphologically with *Citromyces pfefferianus* but showing such physiological divergences as led to its classification as a separate species to which he gave the name *C. siderophilus*. This was investigated in regard to its behavior in connection with iron solutions added to its culture medium, as were also the fungi *Aspergillus niger*, *Penicillium glaucum*, *C. glaber*, *C. pfefferianus*, and several iron bacteria.

Numerous fungi living in iron-containing waters are found to store in their cells, as do the iron bacteria, a considerable amount of hydrated oxid of iron. Most of these are closely allied morphologically with *C. pfefferianus*, but physiologically they differ widely therefrom. *C. siderophilus* thrives in an iron-free culture medium as do the mold fungi, but the addition of 0.5 per cent sulphate of iron causes a notable increase of weight in case of this fungus, while other mold fungi are checked in growth by such addition. *C. siderophilus* shows a particular resistance to the poisonous influence of zinc sulphate. Iron protoxid salts cause no chemically poisonous effect on *C. siderophilus* but a significant promotion of growth. Iron oxid salts are as poisonous to this as to the other fungi. The growth-promoting agent is the ferro-ion, the growth-checking one the ferri-ion. Nondissociating iron salts have no marked influence on growth.

With the presence of iron protoxid in the nutritive solution, the fungus is better able to utilize its carbon supply and can thus flourish in a poorer culture medium. The incrustation of hyphæ with iron is not dependent upon the growth-producing influence of the protoxid, but upon the nature or constitution of the carbon source. It is supposed that the iron-storing bacteria play an essential part in the formation of beds of bog-iron ore.

**On the presence of arbutin in leaves of Grevillea robusta,** E. BOURQUELOT and Mlle. A. FICHTENHOLZ (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 17, pp. 1105-1108).—Since their discovery and investigation of arbutin in species of *Pyrus* (E. S. R., 25, p. 27; 26, p. 327), the authors have extended their studies to other genera and they state that they have been able to identify this glucosid in leaves of *G. robusta*.

**Wood coloring in living spruce,** C. VON TUBEUF (*Naturw. Ztschr. Forst u. Landw.*, 9 (1911), No. 6, pp. 273-276, figs. 2; *abs. in Bot. Centbl.*, 119 (1912), No. 5, p. 98).—An account is given of the author's studies on 3 specimens of spruce, in which the sapwood from roots to topmost twigs, with the exception of the youngest annual rings, showed a blue-black color on being freshly cut, becoming darker for a few days and afterwards remaining unchanged. Microscopic investigations failed to reveal the presence of any organism or any indication of other abnormality. Microchemical tests seemed to show that the coloring was due to impregnation with tannate of iron. This, however, did not seem to interfere with the free passage of water, etc. Root injuries, it is thought, may be a contributing cause. Further investigations are contemplated to induce artificially, if possible, coloration, which appears to be entirely harmless to the living wood.

**The influence of sea water on the distribution of plants,** J. W. HARSHBERGER (*Proc. Amer. Phil. Soc.*, 50 (1911), No. 201, pp. 457-496, pls. 3, figs. 7).—A study was made of the salt content of marsh soils and estuarine waters in their relation to plant distribution along the coast of New Jersey. The hy-

drometer was found very efficient in this respect, and the tolerance to salt of a large number of plants was determined.

As a result of his investigations the author concludes that the salinity of the water, which can be determined by the hydrometer, is the determining factor in the distribution of salt marsh plants, although the texture of the soil, its aeration, and the lines of marsh drainage are influential factors. The author further states that the method applied is also adapted to the study of alkali soils, especially in the western States, and that the farmer can test the presence or absence of salts and their relative amounts in the soil by this method.

**Minnesota plant studies. IV, Minnesota mushrooms, F. E. CLEMENTS** (*Minneapolis, Minn.: Geol. and Nat. Hist. Survey, 1910, pp. 169, pls. 3, figs. 123*).—This publication is designed for plant lovers and for classes in botany in high school and college. It gives simple and concise descriptions of different species of mushrooms occurring within the State.

**Plant introduction for the plant breeder, D. FAIRCHILD** (*U. S. Dept. Agr. Yearbook 1911, pp. 411-422, pls. 6, fig. 1*).—A popular account is given of the work of the Office of Foreign Seed and Plant Introduction of the Bureau of Plant Industry of this Department in securing species and varieties of plants from various parts of the world to be used by plant breeders in their efforts to obtain new combinations of characters that may prove of superior merit or adapted to special environmental conditions.

**The present state of the mutation theory, L. BLARINGHEM** (*Bul. Soc. Bot. France, 58 (1911), No. 8, pp. 644-652*).—The author briefly reviews the recent work of various investigators bearing upon the theory of mutation. In conclusion it is stated that the theory has not been impaired but rather strengthened by the more recent findings of these and related investigations.

**Oenothera nanella, healthy and diseased, H. DE VRIES** (*Science, n. ser., 35 (1912), No. 906, pp. 753, 754*).—Attention is called to the discovery of Zeijlstra regarding the presence of a bacterium in the tissues of dwarf *O. nanella* (*E. S. R., 27, p. 30*). Zeijlstra, however, found that under favorable conditions the side shoots of the dwarfs may become healthy and lose their abnormal characters.

The author carried on some experiments with this dwarf type of *Oenothera* in which plants were grown with a reduced amount of nitrogen and greater quantities of phosphate of calcium. The resulting plants showed all transitions between diseased and normal dwarfs, from which it is inferred that Zeijlstra's discovery instead of diminishing the value of *O. nanella* as a useful mutant has shown means of cultivating it in a healthy condition.

## FIELD CROPS.

[Range improvement, plant introduction, and plant breeding], **J. J. THOENBER, G. F. FREEMAN, and D. F. JONES** (*Arizona Sta. Rpt. 1911, pp. 533-546*).—The conditions on the small and on the large range reserves during the past year are discussed. The last 2 seasons have been generally unfavorable to grazing interests. In this connection a report of progress is made on an experiment in the cutting of fence posts at different seasons.

In the introduction garden over 200 new plants were set out, and descriptions are given of the behavior of Rhodes grass (*Chloris gayana*), Japanese kudzu vine (*Pueraria thunbergiana*), and tamarisks (*Tamarix* spp.).

The work in plant breeding along agronomic and horticultural lines was confined to alfalfa, dates, beans, and sweet corn. During the year 29 new pedigree strains of alfalfa were tested. The yield and quality of hay of 2 strains were again well above the average.

The work with beans up to the present time has brought out the fact that 2 distinct types of these Indian esculent legumes are in existence. One type includes about 23 distinct varieties belonging to the ordinary kidney beans (*Phaseolus vulgaris*), while the other type known as the tepary (*P. acutifolius*) is specifically distinct from any cultivated bean heretofore mentioned in horticultural literature. More than 40 distinct agricultural varieties of the tepary bean were segregated and grown. In 9 experiments covering 3 years' work at Yuma, 2 years at Tucson, and 2 at McNeal, the average yield of the tepary variety was about 4 times the average for the varieties of the kidney beans. The adaptations of these beans to their environment are pointed out.

The relation between contemporaneous silking and tasseling of sweet corn varieties and their yield was pointed out by an experiment carried on during the season. Nineteen stalks having fresh silks and an abundance of pollen and 18 other equally vigorous stalks having the pollen ripe and in process of distribution but on which the silks had not yet appeared were tagged on August 29. When harvested the 19 ears from the stalks with contemporaneous tasseling and silking weighed on an average one and one-half times as much as the average for the ears from the other stalks.

[Work at the Sulphur Springs Valley and Snowflake dry farms], R. W. CLOTHIER and A. M. McOMIE (*Arizona Sta. Rpt. 1911, pp. 529-532*).—Variety tests of corn at the Sulphur Springs Valley dry farm resulted in the best yield of grain from White Flint, 13.1 bu. per acre. Owing to an unfavorable season all yields were rather low, the highest being on a plot, a part of which received some flood water.

Four plots of tepary beans grown by purely dry-farming methods made an average yield of 527 lbs. per acre as compared with an average of 97 lbs. with common pink beans. The tepary beans displayed great resistance to drought as well as remarkable recuperative powers after the drought was broken.

In experiments with supplemental irrigation the experimental plots were watered from December 16 to June 8, the total amount of water given being 3½ in. During the drought in August one plot of milo maize received 3.14 in. of water, a second plot 1.32 in. of water, and a plot of sorghum 1.32 in. of water. The first plot of milo maize yielded 35.7 bu. of clean grain of high quality; the second, 24 bu.; and the sorghum yielded 3.24 tons of forage and 340 lbs. of clean seed per acre.

Work with summer fallowing in 1910 showed that considerable water may be accumulated in the soil during the rainy season but that it is lost before the next rainy season begins. A plot cropped in 1909 and fallowed in 1910 yielded this year 29.9 bu. of milo maize per acre, but this result was attributed to the excellent condition of the soil rather than to fallowing. The lighter types of soil in Sulphur Springs Valley appear to be better adapted to dry farming than the heavier types. Milo maize seems best adapted to grain production and sorghum to the production of forage.

The Snowflake dry farm was broken during the winter of 1909-10 and plantings were made in May, 1910. The crops as well as the land were injured by heavy winds. The grain of milo maize, sorghum, Kafir corn, and Red Dent corn did not mature. The yields of forage on plots irrigated once before planting ranged from 1,680 lbs. for White Flint corn to 4,960 lbs. per acre for Kafir corn. On land summer-fallowed the previous year the lowest yield of forage was 2,400 lbs. per acre for Kafir corn and the highest 4,108 lbs. for broom corn.

[Variety and manurial tests with cereals and root crops], P. H. FOULKES ET AL (*Field Expts. Harper-Adams Agr. Col., and Staffordshire and Shropshire, Rpt. 1911, pp. 1-23, 27-44*).—This continues earlier work (E. S. R., 26, p. 230).

The 8-years' annual average net profit following fertilizer applications to meadow land were greater in case of the use per acre of (1) 2½ cwt. of super-

phosphate and  $\frac{1}{2}$  cwt. of sulphate of potash, and (2)  $2\frac{1}{2}$  cwt. of superphosphate, than in case of other applications of nitrate of soda, superphosphate, sulphate of potash, basic slag, and dung singly or in various mixtures and amounts.

Tables state the yields secured in tests of 19 wheat varieties or strains, 2 of barley, 13 of oats, 12 of sugar beets, and 51 of potatoes.

In a test of 8 different fertilizers an application of 550 lbs. of superphosphate produced a 3-years' average yield of about 1 bu. less barley than did 4 cwt. of potassic superphosphate, at the same expense. Four cwt. of potassic superphosphate applied with 84 lbs. sulphate of ammonia, 130 lbs. nitrate of lime, and 112 lbs. nitrate of soda each supplying the same amount of nitrogen were followed by average yields of  $49\frac{1}{2}$ ,  $50\frac{1}{2}$ , and 48 bu. per acre, respectively. All other applications in this test were surpassed in grain yield by the use of 2 mixtures of kainit, superphosphate, and sulphate of ammonia.

Sugar beets sown in rows 15 in. apart on level ground produced somewhat greater yields than those sown in rows 18 or 21 in. apart. They also slightly excelled plantings 21 in. and 24 in. apart on ridges. In another test seeding at the rate of 20 lbs. per acre produced slightly greater yields than seeding at the rates of 10 and 15 lbs. per acre. In a test of applications of sulphate of ammonia, superphosphate, sulphate of potash, and nitrate of soda, in 7 different mixtures no marked difference in yield was obtained, but the highest yield followed an application of 150 lbs. sulphate of ammonia, 368 lbs. superphosphate, 64 lbs. sulphate of potash, and 100 lbs. nitrate of soda.

The records kept indicate that mangels cost £10 13s. 5d. per acre to produce and yielded 43 tons 8 cwt. of roots as compared with £12 8s. 8d. for sugar beets which yielded 20 tons 9 cwt. of roots. A table states the average weight per root and the sucrose and dry matter contents of the roots grown in the method of sowing, rate of seeding, and fertilizer tests. In a test of 10 compound manures for mangels the highest yield followed the use of 5 cwt. of a mixture which supplied 11.2 lbs. of nitrogen, 67.2 lbs. of soluble phosphates, 44.8 lbs. of insoluble phosphates, and 28 lbs. of potash per acre. The addition of 2 per cent of a radioactive fertilizer to a mixture of steamed bone, sulphite of potash, and nitrate of soda was followed by a yield of 33 tons 13 cwt. of mangels as compared with 29 tons 11 cwt. on the check. A similar 2 per cent addition to another mixture apparently increased the yield of swedes from 12 tons  $18\frac{1}{2}$  cwt. to 15 tons  $11\frac{1}{2}$  cwt.

Fertilizer experiments on grass plats at Blurton and other centers are again reported with results varying somewhat from those of previous years.

Other work reported includes tests of sulphate of ammonia, superphosphate, dissolved bone, sulphate of potash, carbonate of magnesia, nitrate of lime, basic slag, kainit, and salt in various mixtures for potatoes, mangels, and sugar beets in different localities.

**Field experiments in 1910, N. TULAJKOV** (*Kratkii Otchet Polev. Opyt. Bezenchuk. Selsk. Khoz. Opytn. Stantsii, 1910; abs in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 12 (1911), No. 4, pp. 571, 572.*)—This is a report of the work of the Bezenchuk Agricultural Experiment Station in 1910. It states the results of tests of various fertilizers and various systems of fallows for winter rye. Somewhat similar work was done with summer oats and barley. Rates and methods of sowing summer cereals were tested, and variety tests of wheat, oats, millet, potatoes, and sugar beets were conducted.

Plowing 7 in. deep was followed by higher yields of winter cereals than were obtained by plowing either  $3\frac{1}{2}$  or 10 in. deep. In case of summer cereals the best results were obtained by early plowing 7 in. deep, or by late shallow plowing. The potatoes were apparently not influenced by the depth of plowing.

The most favorable area per corn plant appeared to be 336 sq. in.

[Experiments at the Kaiser Wilhelm Institute for agriculture], GERLACH (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 3 [1910], No. 1, pp. 5-30).—Brief progress reports are given of work on irrigation, rate of sowing rye and barley by the Demtschinsky methods, tests of various nitrogen-supplying fertilizers, electro-culture, legume inoculation, and variety tests of rye, wheat, barley, oats, potatoes, and mangels. Citations are given to numerous publications in which results of these tests are more fully stated.

Irrigation experiments of the division of agricultural chemistry in 1909, GERLACH (*Mitt. Kaiser Wilhelms Inst. Land. Bromberg*, 2 (1910), No. 4, pp. 454-465).—These pages report the tests conducted in 1909 with mangels, rye, alfalfa, oats, and potatoes. Tables state in full the results obtained.

It appeared inadvisable to apply nitrate of soda to rye on a very light soil in a dry year unless irrigation was resorted to.

The water economy of dry-land crops, T. H. KEARNEY and H. L. SHANTZ (*U. S. Dept. Agr. Yearbook 1911*, pp. 351-362).—This article in treating of water as a factor in plant growth discusses absorption, transpiration, and water requirements; and in treating of the means by which plants succeed under dry-land conditions describes the adaptations for enduring, evading, and escaping drought.

Some misconceptions concerning dry farming, E. C. CHILCOTT (*U. S. Dept. Agr. Yearbook 1911*, pp. 247-256).—This article discusses precipitation; temperature and length of season; effects of evaporation, hail, and hot winds; diversity of soils; tillage, with special reference to summer fallowing, deep plowing, and preparation of the seed bed; and penetration of the roots into the subsoil in their relation to dry farming.

"The following misconceptions concerning dry farming may be mentioned as among the most serious: (1) That any definite 'system' of dry farming has been or is likely to be established that will be of general applicability to all or any considerable part of the Great Plains area; (2) that any hard and fast rules can be adopted to govern the methods of tillage or of time and depth of plowing; (3) that deep tillage invariably and necessarily increases the water-holding capacity of the soil or facilitates root development; (4) that alternate cropping and summer tillage can be relied upon as a safe basis for a permanent agriculture or that it will invariably overcome the effects of severe and long-continued droughts; and (5) that the farmer can be taught by given rules how to operate a dry-land farm."

Rotations in the corn belt, C. B. SMITH (*U. S. Dept. Agr. Yearbook 1911*, pp. 325-336).—This article discusses cost and profit in corn growing, and points out the disadvantages of continuous corn culture and the advantages of growing corn in rotation. The rotations discussed are corn and oats; corn, oats, and clover; corn, corn, oats, and clover; corn and clover; corn, wheat, and clover as a catch crop; corn, oats, wheat, and clover; corn, cowpeas or soy beans, wheat, and clover; corn and alfalfa; corn and rye; corn and barley; and a number of miscellaneous rotations. The principles governing the establishing of rotations are touched upon and the use of leguminous crops and the applications of fertilizers in corn belt rotations are noted.

Wheat and oats, J. L. BURGESS (*Bul. N. C. Dept. Agr. Sup.*, 32 (1911), No. 10, pp. 24, figs. 5).—Results of variety tests of wheat and oats at the Buncombe and Iredell test farms accompany directions for producing these crops. Earlier wheat and oat work at these farms has already been noted (*E. S. R.*, 24, p. 142).

Report on field trials with varieties of oats and wheat in 1909, T. MILBURN (*Midland Agr. and Dairy Col. Bul.* 7, 1909-10, pp. 63-71).—Steadfast, Marvel, and Sensation, 3 French wheat varieties, yielded on the average about 6 bu.

more grain per acre than did the English varieties Browick Grey Chaff and Carter White Stand Up. The French varieties, especially Marvel, showed many ears affected by loose smut.

Probsteier and White Horse oats gave equal average yields and somewhat outyielded the other 4 varieties tested in the same 5 localities.

**Report on field trials on the manuring of seeds hay in 1909, J. F. BLACKSHAW** (*Midland Agr. and Dairy Col. Bul. 2, 1909-10, pp. 15-25*).—This is a report of tests undertaken in 16 localities for the purpose of determining whether seeds hay (rye grass and clover, one year's seeding) can profitably be treated with artificial fertilizers. Nitrate of soda, superphosphate, sulphate of ammonia, sulphate of potash, kainit, and muriate of potash were applied in various mixtures and on various dates in March and April. Almost equal 3-year average profits followed the use of 200 lbs. of kainit and 50 lbs. of muriate of potash, each in addition to a mixture of 100 lbs. of sulphate of ammonia and 208 lbs. of superphosphate. These applications were all made early in April except the potash which was applied early in March. Each of the 8 other applications tested gave lower average profits.

[Fertilizer and variety tests with meadow hay, swedes, and potatoes] (*Ann. Rpt. Cumberland and Westmorland Farm School, 15 (1911), pp. 8-10*).—The 14-year average yield of meadow hay unfertilized was 30 cwt. per acre; after an application of 10 tons of dung, 42 cwt.;  $\frac{3}{4}$  cwt. nitrate of soda,  $1\frac{1}{2}$  cwt. kainit, and 3 cwt. basic slag, 38 cwt.;  $\frac{3}{4}$  cwt. sulphate of ammonia,  $1\frac{1}{2}$  cwt. kainit, and 3 cwt. of basic slag, 35 cwt.;  $\frac{3}{4}$  cwt. nitrate of soda,  $1\frac{1}{2}$  cwt. kainit, and 3 cwt. of superphosphate, 40 cwt.; and after an application of  $\frac{3}{4}$  cwt. of sulphate of ammonia,  $1\frac{1}{2}$  cwt. of kainit, and 3 cwt. of superphosphate, 36 cwt. of hay per acre.

Two-year average yields of 45 and 48 cwt. of hay per acre, respectively, followed applications of (1)  $\frac{3}{4}$  cwt. of nitrate of lime,  $1\frac{1}{2}$  cwt. of kainit, and 3 cwt. superphosphate, and (2)  $\frac{3}{4}$  cwt. of calcium cyanamid,  $1\frac{1}{2}$  cwt. kainit and 3 cwt. of superphosphate.

Five tons of swedes per acre were secured from the unfertilized plot as compared with  $31\frac{1}{2}$  tons after  $1\frac{1}{2}$  cwt. of nitrate of lime, 2 cwt. kainit, and 5 cwt. of superphosphate; 29 tons after the same mixtures of nitrate of lime and kainit, with 5 cwt. basic slag instead of the superphosphate;  $30\frac{1}{2}$  tons after 1 cwt. nitrate of soda, 2 cwt. kainit, and 5 cwt. superphosphate;  $31\frac{1}{4}$  tons after  $3\frac{3}{4}$  cwt. kainit, and  $7\frac{1}{4}$  cwt. basic slag;  $27\frac{1}{4}$  tons after 12 tons of dung; 32 cwt. after 12 tons of dung,  $\frac{1}{2}$  cwt. nitrate of lime,  $\frac{1}{2}$  cwt. kainit, and  $1\frac{1}{4}$  cwt. superphosphate; and  $31\frac{1}{2}$  tons after an application of 1 ton of ground lime stone in addition to the last named mixture.

A variety test of potatoes is also reported.

**Trials with millets and sorghums for grain and hay in South Dakota, A. N. HUME and M. CHAMPLIN** (*South Dakota Sta. Bul. 135, pp. 309-336, figs. 8*).—This bulletin reports the results of experiments carried on in the years 1907-1910 at Highmore in cooperation with this Department.

The highest average yield of grain secured from any variety of millet from 1907-1910 was 17.6 bu. per acre from common millet. The next highest average yield was 16 bu. per acre from Black Voronezh, this being also practically the yield from Kursk and Tambov millets. The Kursk varieties in 1910 produced a higher yield of hay than the other varieties and yielded 24.7 bu. of grain, the average of the highest yields of the variety for all seasons. Taking the yield of hay and grain into consideration, the authors regard the Kursk millets as the most promising.

It was found that the grain sorghums require a longer time to mature than millet. The average yield of grain per acre for 3 strains of grain sorghum for 3 years (1909-1911), including 2 extremely dry seasons, was 13.7 bu. per acre.

**Alfalfa growing in Alberta.** W. H. FAIRFIELD and G. H. HUTTON (*Canada Expt. Farms Bul.*, 2. ser., 1912, No. 8, pp. 14).—Directions for alfalfa production are given.

Varieties of barley (*Bedfordshire County Council, Agr. Ed. Com., Rpt. Barley and Sugar Beet Plots, 1911; abs. in Jour. Bd. Agr. [London], 18 (1912), No. 12, p. 1034*).—This is a report of a test of 10 varieties of barley on a light sandy soil in 1911. In 5-year average yields, Kinver Chevalier, Goldthorpe, and Prize Prolific stood highest.

Genetic studies of the genus *Brassica*, B. KAJANUS (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 6 (1912), No. 4, pp. 217-237, pls. 4).—These pages report the results of studies of color and form of numerous artificial crosses of different varieties of *Brassica napus*, *B. rapa*, *B. campestris*, *B. oleracea*, *B. lanceolata*, and *Sinapis arvensis* (alba and nigra).

Observations on the inheritance of characters in *Zea mays*, J. BURTT-DAVY (*Separate from Trans. Roy. Soc. So. Africa*, 2 (1912), pt. 3, pp. 261-270).—The author presents statistical and other studies on an ear of corn obtained from a plant grown from a red flint grain and pollinated from other red-grain plants. His studies include row numbers in ears and the inheritance of row numbers and cob color.

When red dent was crossed with a white sugar corn, 2 pairs of characters were segregated in the second generation (1) redness and whiteness, and (2) starchiness and sugaryness in approximately these proportions: (1) Red, starchy 56.25 and sugary 18.75 per cent, and (2) white, starchy 18.75 and sugary 6.25 per cent. One grain distinctly showed a starchy character in one-half and a sugary character in the other.

Within certain limits the number of rows of grain per ear were found subject to fluctuations. Crossing an 8 row with an 18 row type produced an intermediate type in which 10, 12, and 14 row ears appeared, the 12-row type greatly predominating.

Cooperative tests of corn varieties, E. R. MINNS (*New York Cornell Sta. Bul.* 314, pp. 395-410, figs. 3).—This bulletin summarizes the results of testing varieties of corn in cooperative experiments carried on during 3 years.

It was found that elevation above sea level, as influencing the climate of a locality, and the type of soil, were highly important factors in corn growing. A high elevation combined with a soil type not suited to corn caused a failure or gave very poor results with varieties that gave good yields in other localities. The better type of soils at lower elevations gave much better results, especially when dent varieties were grown.

For elevations of 1,000 ft. or more, varieties of flint corn appeared better adapted for the production of ripe grain and stover than dent varieties, and for ensilage there were also a few good flint varieties and some early dent varieties that were preferable to very late dent corn. At elevations ranging from 600 to 1,000 ft. some flint varieties gave better yields of mature corn than dent varieties of equal earliness, while for ensilage both dent and flint varieties were found sufficiently productive in a normal season. For elevations lower than 600 ft., dent corn produced more satisfactory yields of grain and stover or silage than the flint varieties. These experiments were not carried on long enough to determine the individual varieties best adapted for either grain or fodder production in the different localities.

Cotton improvement on a community basis, O. F. COOK (*U. S. Dept. Agr. Yearbook 1911*, pp. 397-410).—This article discusses the desirability and feasibility of cotton improvement in the United States, and points out ways and

means by which this may be accomplished on a community basis. Special attention is given to the preservation of the uniformity of varieties.

"In order to maintain uniformity and produce commercial quantities of one kind of cotton communities should limit themselves to the cultivation and selection of a single superior variety. The choice of the variety to be grown, the production of good seed, the determination of the date of planting and the methods of cultivation, the harvesting, ginning, storing, and marketing of the crop are all problems that can be solved to much better advantage by community cooperation than by individual planters working alone."

Fibers used for binder twine, L. H. DEWEY (*U. S. Dept. Agr. Yearbook 1911*, pp. 193-200, pls. 3).—This article points out the requirements of binder twine fiber and gives descriptions of the following plants from which such fibers are obtained: Abacá (*Musa textilis*), henequen (*Agave fourcroydes*), sisal (*A. sisalana*), Phormium or New Zealand hemp (*Phormium tenax*), Mauritius (*Furcraea foetida*), cabuya (*F. cabuya* and *F. cabuya integra*), Manila maguey (*Agave cantala*), mescal magney (*Agave* sp.), zapupe (*A. zapupe*, *A. lespinassei*, and *A. deweyana*), flax, and hemp.

Manuring of hops, B. DYER (*Abs. in Jour. Bd. Agr. [London], 18 (1912), No. 11, p. 942*).—The report states the yields secured in tests of phosphate, potash, nitrate of soda, and dung, applied singly and in various mixtures to hops during the 16-year period 1896-1911 (*E. S. R.*, 12, p. 46).

The use of more than 4 cwt. of nitrate of soda was followed by very slight increases of crop for the extra quantity. Chemical analyses and the estimation of values showed no difference between the hops grown with natural and those grown with artificial fertilizers. Even after liberal fall or winter applications of natural or artificial fertilizers the author believes that a spring application of 4 cwt. of nitrate of soda per acre is safe and profitable even in a wet season.

Orchard grass seed from different countries, F. G. STEBLER and A. VOLKART (*Landw. Jahrb. Schweiz, 25 (1911), No. 2, pp. 171-188, figs. 4*).—The authors briefly review some work of others and report the results of tests of seed from France, New Zealand, America, Hungary, Holland, and certain German provinces.

Experiments on paddy cultivation during the years 1909-1911, L. C. COLEMAN and D. G. RAMA CHANDRA (*Dept. Agr. Mysore, Gen. Ser. Bul. 2, 1912, pp. IV+44, pls. 2*).—This reports mainly results of variety, fertilizer, and cultural tests of rice.

Seed which sank in a solution of one part of salt to two parts of water had a higher germination percentage and greater weight per kernel, as well as a higher density, than that which floated.

Growth of sugar beet (*Bedfordshire County Council, Agr. Ed. Com., Rpt. Barley and Sugar Beet Plots, 1911; abs. in Jour. Bd. Agr. [London], 18 (1912), No. 12, pp. 1034, 1035*).—This is a report of experiments conducted to determine the feasibility of growing sugar beets in various districts, including the results of variety, cultural, and fertilizer tests. The sugar percentage varied little.

Nitrogen fertilization and the composition of sugar beets, H. SÁNDOR (*Kísérlet Közlem., 14 (1911), No. 5, pp. 655-675, figs. 2*).—Increasing nitrogen applications on pure sandy soil, low in humus, increased the beet yield, especially the yield of leaves. The lowest sugar content followed the lowest nitrogen applications. The proportion of dry matter was apparently not affected, except in case of the nonsugar substances. Very heavy nitrogen fertilization increased the injurious nitrogen disproportionately, but the increase was not regular when potash and phosphorus were present in sufficient quantities.

**Manuring of swedes** (*Univ. Col. Reading, Dept. Agr. and Hort. Bul. 10, 1910; abs. in Jour. Bd. Agr. [London], 18 (1912), No. 11, p. 942*).—This is a report of the results of tests at 5 points in Oxfordshire of superphosphate, steamed bone flour, and basic slag, singly and mixed with sulphate of potash and sulphate of ammonia, or in case of basic slag, with nitrate of soda instead of sulphate of ammonia. The results at different points varied, the deciding factor apparently being the amount of lime in the soil.

**The production of new and improved varieties of timothy**, H. J. WEBBER ET AL. (*New York Cornell Sta. Bul. 313, pp. 337-391, figs. 42*).—A previous report on this line of work has already been noted (*E. S. R., 23, p. 536*). This bulletin discusses timothy as an agricultural crop, describes the methods used in the Cornell breeding and selection experiments, points out some of the more striking variations observed, and gives notes on testing selected plants of different types, testing the transmission of type in selections when grown from seed, and on the method of isolating a pure type and multiplying the seed. A method of improving timothy and recommended for the use of farmers is also given. An appendix to the bulletin summarizes the work reported by H. J. Waters (*E. S. R., 26, p. 265*).

A table on the transmission of yield in timothy by clonal and seed propagation with 16 plants from each individual, the different rows being placed 4 ft. apart and the plants 3 ft. apart in the rows, shows clearly the great range of variation in this character. Taking the average yield for the second and third years of all the 16 plants of one kind, the lightest yielder averaged 1.005 oz. per plant and the heaviest 20.274 oz. per plant. Among the 200 plants entering into this test, 5 gave for the 2 years an average yield per plant of 1 lb. or more, while 39 gave average yields of less than  $\frac{1}{2}$  lb. per plant.

In a study of the effect of self-fertilization on vigor, it was found that in 9 tests with different types, the average yield per plant for all plants tested was for the original plants 9.307 oz., for the clons 8.769 oz., for the open-fertilized seed 6.963 oz., and for the self-fertilized seed 5.243 oz. The yield of the original plants in this test represents a 3-year average, while in the other cases the result is based on a 2-year average.

A test of the new varieties of timothy gave as average yield in 1910 for 17 new sorts of 7,451 lbs. of field-cured hay per acre, while the check plats sown with a good grade of commercial seed gave an average yield of 6,600 lbs. In 1911, a much more unfavorable season than the preceding year, the 17 new sorts yielded 7,153 lbs. per acre and the check plats 4,091 lbs. The actual average increase in favor of the new varieties was 851 lbs. per acre in 1910 and 3,062 lbs. in 1911. The hay produced by the new varieties was apparently of superior quality owing to the retention of a fresh green appearance and leafiness. This is considered due in the main to the greater rust-resistant character of the new sorts and to the fact that the majority of them were selected as possessing the ability to retain their leaves and stems green until the heads have become fully matured.

**Correlation and inheritance in *Nicotiana tabacum***, H. K. HAYES (*Connecticut State Sta. Bul. 171, pp. 3-45, pls. 5*).—The characters studied with reference to correlation and inheritance were number of leaves per plant, height of plant, average area of leaf, and length and breadth of leaf. The types of tobacco studied in this connection were Uncle Sam Sumatra, Broadleaf, Havana, Small-leafed Sumatra, and Cuban. With the exception of the Broadleaf strain, these types had been inbred for a number of years and were uniform to type.

In the study of the correlation of parts, the Broadleaf and Small-leafed Sumatra types were used. In these 2 types and in the first and second

generation crosses between them, the Sumatra being the female parent, there was a positive correlation between number of leaves and height of plant, although in all but one case this was less than +0.5. It was further shown that a large number of leaves was associated with a slightly smaller leaf area and that the longer leaves were on the average also the broader ones.

The inheritance of characters was studied in crosses between Cuban and Uncle Sam Sumatra, Uncle Sam Sumatra and Cuban, Small-leaved Sumatra and Broadleaf, and Havana and Cuban, the first mentioned being the female parent in each case. Environment was found to be an important factor in producing fluctuating variabilities. The number of leaves per plant under normal or nearly normal conditions was least affected. The reciprocal crosses appeared to be equal within the limits of fluctuating variability. The  $F_1$  generation was intermediate in the character studied and was, as a rule, somewhat larger than the average of the parents. All of the characters considered except the number of leaves per plant showed added vigor. This generation did not appear more variable than the parents, the variability being slightly greater than the average of the parents in 6 cases and less in 5. Different variates in  $F_1$  gave similar results in  $F_2$  which is regarded as indicating that the fluctuating variation was due to environment. The  $F_2$  generation was more variable than the parents. When sufficient numbers of variates were studied, the  $F_2$  showed a range of variation equal to the combined range of the parents and the  $F_1$  generation. Leaf number and average leaf area appeared to be inherited independently, and it is pointed out that this being the case the desirable leaf-size characters of one variety may be combined with the number of leaves of another form. The results also showed some variation in the correlation between height of plant and number of leaves, and a large positive correlation was apparent between length and breadth of leaf.

The author concludes that the results are entirely in accord with the Mendelian interpretation of quantitative characters by the hypothesis that a multiplicity of factors exists, each independently inherited and capable of adding to the character. Observations on the cured leaf of several  $F_1$  crosses indicated that the leaves of this generation are low in quality.

The prospects for wheat cultivation in Natal. E. R. SAWER (*Agr. Jour. Union So. Africa*, 2 (1911), No. 5, pp. 542-561, figs. 12).—The author gives a classification of wheats, summarizes work of other experimenters, and states the results of variety and irrigation tests at Weenen.

Results of seed tests for 1911. F. W. TAYLOR (*New Hampshire Sta. Bul.* 156, pp. 14).—This bulletin presents in tabular form the results of seed tests made in 1911, and gives in addition the text of the law of New Hampshire passed in 1909 for the purpose of regulating the sale of agricultural seeds. During the year 72 samples of seed were examined as against 238 for the year before.

Purity and germination of agricultural and vegetable seeds sold in North Carolina. O. I. TILLMAN (*Bul. N. C. Dept. Agr.*, 32 (1911), No. 10, pp. 78, pls. 8, figs. 2).—The text of the North Carolina pure seed act follows tables stating the results of purity and germination tests of seeds collected and analyzed in accordance with its provisions. Tests of samples submitted by correspondence are also reported.

Eradication of charlock and wild mustard. C. SÁNDOR (*Kisérlet Közlem.*, 14 (1911), No. 5, pp. 720-727).—All the field mustard was killed when sprayed with a 20 per cent solution of iron sulphate, but the destruction was less complete in case of charlock or wild radish. A proprietary powder was also tested.

Johnson grass control. F. W. WILSON (*Arizona Sta. Rpt.* 1911, pp. 549, 550).—This article deals with the control of Johnson grass and gives directions

for its eradication. The most satisfactory method employed on the station farm consisted in keeping the grass from seeding by close grazing or mowing and later digging up the roots.

### HORTICULTURE.

The present status of horticulture in the Philippines and its outlook for the future. P. J. WESTER (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 7, pp. 353-364).—The author reviews the horticultural conditions in the past and present, discusses the more prominent fruits and their possibilities, and calls attention to the neglect of nearby important markets.

Report of the Government Horticultural Gardens, Lucknow, for the year ending March 31, 1912. H. R. C. HAILEY (*Rpt. Govt. Hort. Gardens Lucknow, 1912*, pp. 10).—This comprises a short progress report relative to the administration of the gardens, together with acclimatization and other experimental work conducted during the year with fruit and food producing plants, and other trees and plants of economic value.

Report of the Government Botanical Gardens, Saharanpur, for the year ending March 31, 1912. H. R. C. HAILEY (*Rpt. Govt. Bot. Gardens Saharanpur, 1912*, pp. 9).—A progress report of the routine and miscellaneous work conducted during the year, including also acclimatization and other experimental work conducted with fruits, vegetables, and other economic plants.

The vegetable garden, W. S. BLAIR (*Ottawa: Govt., 1912*, pp. 17).—A brief popular treatise including cultural details for the more important vegetables.

Annotated list of Philippine vegetables, P. J. WESTER and O. W. BARRETT (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 7, pp. 371-374, pl. 16).—This comprises a list of 47 Philippine vegetables, including local and botanical names together with brief notes on their character, economic value, and distribution.

Annotated list of Philippine fruits, P. J. WESTER and O. W. BARRETT (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 7, pp. 365-370, pls. 2).—A list similar to the above is given for 66 kinds of fruits.

Recent plant introductions into the Philippines. P. J. WESTER (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 7, pp. 391-398).—A review of the work of the Philippine Bureau of Agriculture in the introduction of fruits, vegetables, cereals, forage crops, and other economic plants.

Marcottage: Its utilization in the Tropics, H. H. BOYLE (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 7, pp. 385-390, figs. 3).—This comprises a short résumé of the different methods of layerage employed in the Philippines, in the United States, and in Europe.

Anonaceous fruits and their propagation, P. J. WESTER (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 6, pp. 298-304, fig. 1).—Methods of propagating the cherimoya (*Anona cherimolia*), the sugar apple (*A. squamosa*), the soursoy (*A. muricata*), and the custard apple (*A. reticulata*) are described.

Promising new fruits, W. A. TAYLOR and H. P. GOULD (*U. S. Dept. Agr. Yearbook 1911*, pp. 423-433, pls. 8).—In continuation of similar articles (E. S. R., 25, p. 540) historical notes with descriptions and color plates are given of the following new and little-known fruits that are considered worthy of more extensive trial: Cornell, San Jacinto, and Shiawassee apples; Laire and Moncelt plums; Panariti grape; the Thomson orange; Ayer pear; and Russell peach.

Orchard notes, W. W. BONNS (*Maine Sta. Bul. 199*, pp. 33-56, pls. 8, fig. 1).—A progress report on experimental work in pomology conducted by the station since its acquisition of the Highmoor Farm in 1909, including also some pomological notes discussing a successful method of emasculating blossom buds, teratology, and winter injury.

During 1910 and 1911 the Highmoor orchards received a general renovation and one block of trees was divided to include spraying experiments, previously noted (E. S. R., 27, p. 440), sheep pasturage, hog pasturage, and fertilizer experiments. A sod plat was retained as a check.

As compared with the previous condition of the orchards, the work of renovation was highly successful. The chief factor accountable for low production per tree was found to be the lack of cultivation. Lack of vigor and vastly insufficient growth were everywhere evident in the sheep, hog, and sod plats. No conclusions can be drawn as yet relative to the comparative effect of inorganic versus organic fertilizers.

The method of emasculating blossom buds at the station consists in laying back the enfolded petals and removing the anthers with a small portion of the filament by means of a small, thin-bladed scalpel with thin cutting edge tapering to an acute V. The fruit obtained in the crossing work of the past season all resulted from buds emasculated in the above manner. No fruits were set on blossoms in which the petals were removed before castration.

Following the winter of 1910-11 a considerable amount of winter injury to the trunks of trees was noted in a number of localities. This injury took the form of a severe loosening and splitting of the bark of the trunk. In less serious cases longitudinal splits occurred, extending through the living tissues to the wood. Although the cause of the injury is not definitely known it is suggested that it may be due to insufficient soil drainage and a sudden temperature drop below the freezing point following a period of warm weather.

**Apple growing, M. C. BURRITT** (*New York, 1912, pp. 177*).—A popular work dealing especially with the small apple orchard on the general farm. The successive chapters discuss the outlook for the growing of apples, planning for the orchard, planting and growing the orchard, pruning the trees, cultivation and cover cropping, manuring and fertilizing, insects and diseases affecting the apple, the principles and practice of spraying, harvesting and storing, markets and marketing, some hints on renovating old orchards, and the cost of growing apples.

**Apple growing in the Pacific Northwest, C. I. LEWIS ET AL.** (*Portland, Oreg., 1911, pp. 215, figs. 60*).—A condensation of lectures, experiments, and discussions conducted by various authorities relative to different phases of apple growing.

**The fibro-vascular system of the apple and its functions, D. MCALPINE** (*Proc. Linn. Soc. N. S. Wales, 36 (1911), pt. 4, pp. 613-625, pls. 5*).—A detailed study of the structure of the mature apple with special reference to the fibro-vascular system. A number of illustrations of various phases of the vascular system are included.

**The fibro-vascular system of the pear, D. MCALPINE** (*Proc. Linn. Soc. N. S. Wales, 36 (1911), pt. 4, pp. 656-663, pls. 4*).—A briefer study, similar to the above, of the fibro-vascular system of the pear.

**Experiments with artificial root pressure, C. VALLEJO** (*Bol. Min. Agr. [Buenos Aires], 14 (1912), No. 4, pp. 386-396, figs. 9*).—The experiments reported comprised the introduction of various nutrient solutions into the roots of a number of young newly transplanted Kieffer pears. The normal solution consisted of calcium and potassium nitrates, potassium chlorid, sodium phosphate, magnesium sulphate, and distilled water. In the variant solutions one or the other of the above ingredients was omitted. The experiment was conducted primarily to determine whether an excessive supply of nutrients would be conducive to the formation of fruit buds.

Negative results were secured with reference to the formation of fruit buds. No difference was noted between the various solutions used as measured by the

condition of the trees. The introduction of a nutrient solution into the root appears to have a temporary value in re-establishing growth conditions in newly transplanted trees.

[**Peach culture**] (*Ontario Dept. Agr. Bul. 201, 1912, pp. 59, figs. 24*).—This is a two-part bulletin dealing with the culture and diseases of the peach.

I. *Peach growing*, by F. M. CLEMENT (pp. 1-31).—This discusses the methods of growing peaches as based on experience and observation in the Niagara Peninsula, as well as on the results of experimental work in different parts of the United States.

II. *Peach diseases*, by L. CAESAR (pp. 33-59).—This describes the most important peach diseases of Ontario, together with methods for their control.

**Artificial date ripening**, A. E. VINSON and W. H. ROSS (*Arizona Sta. Rpt. 1911, pp. 563-565*).—Date ripening investigations (E. S. R., 25, p. 745) were continued in 1911. The season was exceptionally unfavorable to natural ripening of dates and demonstrates the desirability for ripening all classes of dates artificially. Tests made during the year indicate that evenness of maturity is one of the most important factors in successful date culture in most parts of southern Arizona. Varieties that mature evenly can be artificially ripened without loss into high quality fruit in the most adverse seasons, whereas varieties that mature less evenly, such as Rhars, will yield at any given time only a small percentage of first quality fruit when artificially ripened.

Two lots of Rhars dates ripened by nitrous ether vapor produced 55 and 59 per cent, respectively, of first quality fruit. An attempt to ripen artificially sound Deglet Noor dates by heat yielded only an inconsiderable amount of usable but inferior fruit.

Notes are given on promising varieties of dates for southern Arizona.

**Marketing problems**, A. W. MORRILL (*Arizona Sta. Rpt. 1911, pp. 554, 555*).—A brief discussion of suggested improvements in the marketing of the Arizona navel orange crop.

**The reduction of waste in marketing**, F. ANDREWS (*U. S. Dept. Agr. Yearbook 1911, pp. 165-176*).—In this article the author describes the working of 2 general plans which have been extensively used during the past 10 or 15 years to reduce the cost of marketing fresh fruits and vegetables. One plan is used by shippers to distribute consignments among cities and towns in such a manner as to avoid a glut; the other is employed by transportation companies in moving perishable freight quickly, and in rerouting it even when it is on the way to market.

**The Weather Bureau and the cranberry industry**, H. J. COX (*U. S. Dept. Agr. Yearbook 1911, pp. 211-222, pls. 4*).—In addition to a general account of the cranberry industry in the United States, investigations into frost and temperature conditions in Wisconsin cranberry marshes are described. It is stated that the investigations, which were conducted with the view of facilitating the forecasting of frost, have proved of great advantage to the growers.

**Vines and vine culture**, A. F. BARRON (*London, 1912, 5. ed., rev. and enl., pp. XVI+211, figs. 95*).—A treatise on amateur and commercial grape growing in the conservatory and vineyard, including also chapters dealing with selection of grapes for special purposes, the classification of grapes, and varieties of European and American grapes.

**The Oppenheim method of tying up vine shoots**, F. KOBER (*Allg. Wein Ztg., 25 (1910), No. 16, pp. 159-161; 26 (1911), No. 16, pp. 163, 164; 27 (1912), No. 4, pp. 34, 35; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 3, pp. 695-699, figs. 2*).—A system of training up grape vines between parallel movable sets of wires is here described and illus-

trated. This system, which has been employed for a number of years by the Viticultural School at Oppenheim, Hesse, is said to be a labor-saving method for tying young vine canes.

Early or late pruning, L. RAVAZ (*Taille Hâtive ou Taille Tardive. Montpellier, 1912, pp. 15*).—This comprises a progress report of experiments started in 1905 to determine the effect of pruning grapes at different times of the year on the vigor of the vine and production. The experiments were conducted in a young vineyard planted in 1905. Different rows were pruned as follows: Immediately after the vintage; at the time of leaf fall; during the dormant period; at the time the eyes first appeared; during the budding period; and when the terminal shoots were about 2 in. long. The shoots in all cases were cut back to 2 eyes.

A study of the results to date leads the author to conclude that pruning after the terminal shoots have started serves as a partial protection against spring frosts and increases production without materially affecting the vigor of the vine. The chief value of this late pruning appears to be due to the removal of the outlying buds which are the first to open in the spring.

The author questions whether the bleeding caused by pruning after the shoots have started is harmful. To avoid this, however, and still prevent the vines from starting too early in the spring all unnecessary growth may be removed during the dormant period, the fruiting shoots shortened somewhat, and all eyes removed except the two nearest the base. Since the basal eyes are affected by the length of the shoot rather than by the number of eyes beyond them they will not start any earlier in the spring for having the remaining eyes removed. The author found that sulphate of iron, which has been suggested as a dressing to prevent bleeding, has a tendency to increase the sensibility of the tissues to cold.

Contribution to the physiology of the graft.—Influence of the stock on scion, G. RIVIÈRE and G. BAILHACHE (*Jour. Soc. Nat. Hort. France, 4. ser., 13 (1912), June, pp. 360-363*).—In continuation of previous investigations (E. S. R., 24, p. 641), experiments with the Chasselas doré grape grown on various American stocks and on its own roots are reported.

The authors conclude that the operation of grafting in itself causes only slight modifications in the nature of the product of the scions. The scion and its products, however, do appear to be modified by the particular stock used, certain stocks increasing and others diminishing the particular characteristics of the scion.

The hybrid direct bearers in the valley of the Rhone in 1911, A. DESMOULINS and V. VILLARD (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 33 (1912), Nos. 27, pp. 13-21; 28, pp. 49-56*).—As in previous years (E. S. R., 24, p. 545), notes and data are given of a large number of hybrid direct bearing grapes. The hybrids are classified relative to their resistance to the serious drought in 1911, as well as their resistance to mildew, the nature of the soil best suited for them, and according to the intensity of the coloration of their must.

Report of the enological station relative to its history, developments, and results obtained from the time of its establishment up to November 31, 1910, V. C. M. DE ZÚÑIGA (*Estac. Enol. Haro Mem., 1910, pp. 32, pls. 3*).—This report reviews the work of the enological station, Haro, Spain, for the period 1892 to 1910.

Report of the enological station of Haro for 1911, V. C. M. DE ZÚÑIGA (*Estac. Enol. Haro Mem., 1911, pp. 81*).—This report is similar in character to those noted in previous years (E. S. R., 25, p. 840), summarizing the progress made in laboratory and field investigations, assistance rendered, etc.

Cacao experiments, 1911 (*Jour. Bd. Agr. Brit. Guiana*, 5 (1912), No. 4, pp. 232-234).—Data are given showing the yields of cacao from the manurial experiment fields at the Onderneeming School Farm in 1911.

During the last 3 years the highest yield has been secured from heavily mulched plats. On the other hand an increased yield has been secured more cheaply by the application of sulphate of potash and superphosphate of lime.

Street trees, J. J. LEVISON (*Proc. Amer. Assoc. Park Supts.*, 13 (1911), pp. 35-47, figs. 4).—A paper and discussion dealing with the fundamental principles of street tree planting, care, and selection of species.

Native trees as hedge plants, A. W. GREEN (*Jour. New Zeal. Dept. Agr.*, 4 (1912), No. 6, pp. 444-448, figs. 6).—Notes are given on a number of New Zealand trees which are proving desirable as hedge plants.

## FORESTRY.

Economic woods of the United States, S. J. RECORD (*New York*, 1912, pp. VII+117, pls. 6, figs. 15).—This is a guide or manual for the identification of the economic woods of the United States, including a discussion of the structural and physical properties of wood. Part 1 deals briefly with the more important structural and physical properties of wood, the structural properties being based upon the character and arrangement of the wood elements, and the physical properties being based upon the molecular composition of the wood elements. Part 2 comprises an artificial classification of the economic woods of the United States based upon the structural and physical properties of wood as discussed in part 1.

Frequent references are made to the literature on various phases of the subject, and lists are given of publications dealing with general classifications, characteristics, and uses of woods.

Commercial guide to the forest economic products of India, R. S. PEARSON (*Calcutta*, 1912, pp. IX+155+XIII, pls. 7).—Chapter 1 comprises a short résumé of the distribution and classification of the many types of forests found in British India, together with a note on the financial working of these forests. Chapter 2 discusses a large number of the more common timber trees of India and Burma, relative to the distribution, quality, and uses of the timber, approximate value, and yields in various localities. Chapter 3 deals with such minor products as cutch, gums, fibers, resins, tan and dye products, oil seeds, etc.

Experiments with jack pine and hemlock for mechanical pulp, J. H. THICKENS (*U. S. Dept. Agr., Forest Serv. [Pamphlet]*, 1912, pp. 29, pls 15, fig. 1).—Tests conducted cooperatively by the Forest Service and the American Pulp and Paper Association to determine the value of hemlock and jack pine as substitutes for spruce pulpwood are here reported in detail, including a discussion of the equipment used in the experiment, methods employed, calculation of results, comparison of yields, factors which influence quality and production, and a microscopic comparison of experimental pulps and commercial standards. Samples of paper produced from the various tests accompany the bulletin.

Not only have very promising sheets of pulp been obtained from both the hemlock and jack pine, but paper has been made from them on commercial machines, operating at high speed and under all other conditions of actual commercial practices, which has the strength, finish, and appearance of the standard news paper. The production per grinder, the horsepower consumption per ton, and the yield per cord approximate the averages which obtain in the grinding of spruce. Pulps composed of mixtures of hemlock, spruce, and jack pine in different proportions, which compare very favorably with the ordinary spruce ground wood, have also been obtained. The author concludes that

both jack pine and hemlock may be advantageously used, either singly or in various combinations, at least in the cheaper grades of paper.

**Note on the antiseptic treatment of *Pinus excelsa* and *P. longifolia* sleepers with *Avenarius carbolineum* oil at Jagadhari, R. S. PEARSON** (*Indian Forester*, 38 (1912), No. 7, pp. 329-332).—The method and results of treatment of over 700 railroad ties with *A. carbolineum* oil is described in detail.

**Harvesting and preparation of balata in French Guiana, V. BOUCHER** (*Bul. Off. Colon. [France]*, 5 (1912), No. 55, pp. 209-213).—A short descriptive account.

***Hevea brasiliensis* or Para rubber, H. WRIGHT** (*London and Ceylon, 1912, 4. ed., pp. XX+542, pls. 39, figs. 25*).—This work treats of the botany, cultivation, chemistry, and diseases of Para rubber. The successive chapters discuss the history of Para rubber and of rubber plantations; botanical sources of rubber; climatic conditions and rate of growth of *Hevea brasiliensis*; planting operations and methods of cultivation; cultivation of catch and intercrops; Hevea rubber soils and manuring; tapping operations and implements; how, where, and when to tap; methods in vogue on notable estates; effects of tapping; tapping and yields in the Amazon region, Malaya, Ceylon, South India, Dutch East Indies, Borneo, Africa, etc.; general considerations affecting yields; physical and chemical properties of latex; production of rubber from latex; the theory of coagulation; purification of rubber and washing machines; the drying and smoking of rubber; forms, branding, packing, handling, characters, and comparative value of plantation rubber; chemical and physical properties and testing of rubber; manufacture and composition of rubber articles; properties, uses, and distribution of seeds; diseases and pests of Hevea rubber trees; costs of production on estates; and estimated costs of planting in the middle east.

**The influence of light on the quality of oak wood in the high-forest of the Vosges, P. GALLAND** (*Rev. Eaux et Forêts, 51 (1912), No. 15, pp. 459-464*).—A study of oak forests in the Vosges leads the author to conclude that when oak trees are subjected to much greater light conditions than those under which they have been developed, they deteriorate in value to such an extent that where they occur in regeneration areas they should be removed before the work of regeneration is commenced. The ideal light condition for an oak forest is one in which the top of the tree is in open sunlight and the base in shade.

**Establishment of mixed stands of spruce and beech as well as of pine and beech as the best means of avoiding the dangers which threaten pure stands of conifers, and for the improvement of the soil, D. TIEMANN** (*Forstw. Centbl., n. ser., 34 (1912), Nos. 6, pp. 297-309; 7, pp. 345-353*).—In this article the author advocates the growing of spruce and pine in mixtures with beech in order to lessen such dangers as storms, snow, fire, and insect attacks which often do serious injury to pure stands of spruce and pine. The importance of mixed stands as a means of soil improvement is also discussed.

**Winterkilling of evergreens, C. V. NASH** (*Jour. N. Y. Bot. Gard., 13 (1912), No. 151, pp. 110-120*).—A large number of both coniferous and broad-leaved evergreens are listed and discussed relative to their behavior during the severe winter of 1911-12.

**Forest conditions in Indiana, S. COULTER** (*Proc. Ind. Acad. Sci., 1909, pp. 447-462*).—This comprises a study of forest conditions in Indiana, including recommendations relative to the maintenance of an adequate timber supply in the State.

**Tree planting by farmers, C. R. TILLOTSON** (*U. S. Dept. Agr. Yearbook 1911, pp. 257-268, pls. 3*).—This article discusses briefly, for the region east of Nebraska and north of Tennessee and North Carolina, the best trees to plant, the methods to be followed in planting them, and the products they yield.

The business aspect of National Forest timber sales, T. D. WOODBURY (*U. S. Dept. Agr. Yearbook 1911*, pp. 363-370, pls. 4).—A popular article discussing the various economic operations involved in the disposal of mature timber on the National Forests, including a comparison of the items of cost of operations in National Forest timber and in private timber areas.

Report on the forest administration of the Central Provinces for the year 1910-11, H. H. FORTEATH, H. H. HAINES, and A. W. BLUNT (*Rpt. Forest Admin. Cent. Prov. [India], 1910-11*, pp. 59+LXXV, pl. 1).—This comprises the reports of the conservators of forests relative to the administration of the state forests in the Northern, Southern, and Berar Circles of the Central Provinces for the year 1910-11. A review of the work by the chief conservator of forests is also given. All of the important data relative to alterations in forest areas, forest surveys, production, yields in major and minor products, revenues, expenditures, etc., are appended in tabular form.

Administration report of the forest circles in the Bombay Presidency, including Sind, for the year 1910-11, O. H. L. NAPIER ET AL. (*Admin. Rpt. Forest Circles Bombay, 1910-11*, pp. 172).—This is a report similar to the above relative to the administration of the state forests in the Bombay Presidency, including Sind, for the year 1910-11.

Progress report of forest administration in Coorg for 1910-11, H. TIREMAN (*Rpt. Forest Admin. Coorg, 1910-11*, pp. 8+12).—A report similar to the above relative to the administration of state forests in Coorg for the year 1910-11.

## DISEASES OF PLANTS.

Some recent work on fungus diseases of plants, L. H. PAMMEL (*Trans. Iowa Hort. Soc., 46 (1911)*, pp. 188-198).—Summaries are given of a number of publications relating to plant diseases, most of the literature noted being that of American authors.

Fungus diseases in Iowa for the year 1911, L. H. PAMMEL (*Trans. Iowa Hort. Soc., 46 (1911)*, pp. 172-179, pl. 1, figs. 10).—Notes are given on miscellaneous fungus diseases noted during the period covered by the report, together with a discussion of the relation between meteorological conditions and the occurrence of different fungi.

Report on plant diseases observed during 1911, SOFIE ROSTRUP and F. K. RAVN (*Tidsskr. Landbr. Plantcarl, 19 (1912)*, No. 1, pp. 44-76).—This report gives an account of the fungus diseases and insect pests observed in Denmark during 1911.

Report on vegetable pathology, H. TRYON (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1910-11*, pp. 74-78).—Notes are given on a number of fungus and other diseases of field, orchard, and garden plants, and a discussion is presented of the enforcement of the diseases of plants act of Queensland, 1896.

Relations of parasitic fungi to their host plants.—I, Studies of parasitized leaf tissue, E. S. REYNOLDS (*Bot. Gaz., 53 (1912)*, No. 5, pp. 365-395, figs. 9).—Details are given of studies made, with negative results, on about a dozen species to ascertain, if possible, any characteristic differences between parasitic action on leaf cells and on those of other parts of the plant. An extensive bibliography is appended.

Studies of some new Citromyces, G. BAINIER and A. SARTORY (*Bul. Trimest. Soc. Mycol. France, 28 (1912)*, No. 1, pp. 38-49, pls. 2).—The results of a study of a number of new species of Citromyces are given, and 3 new species are described. The authors call attention to this group of fungi which possesses the property of producing citric acid from such media as glucose, etc., and state that while the fungi have morphological characters which make it impossible to

differentiate them, they do not produce the same effect when grown on culture media. They think the name *Citromyces* an inappropriate one, as other organisms that can not be referred to this genus produce citric acid from glucose, etc.

**On root tumors**, A. STIFT (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 41 (1912), No. 2, pp. 241-249, figs. 6).—A discussion is given of a beet root deformation, claimed to be different as to character and cause from the tumorous growths usually described. The shape of growth, which in this case involves the main root and differences of composition are held to support this claim.

**The causes of beet blight**, L. PETERS (*Arb. K. Biol. Anst. Land u. Forstw.*, 8 (1911), No. 2, pp. 211-259, figs. 12; *abs. in Ztschr. Pflanzenkrankh.*, 22 (1912), No. 3, pp. 179, 180).—The author holds that this disease is caused by *Pythium debaryanum*, *Phoma betæ*, and *Aphanomyces lavis*. The last named has not before been pointed out as a probable factor in this disease.

**Investigations of the potato fungus *Phytophthora infestans***, L. R. JONES, N. J. GIDDINGS, and B. F. LUTMAN (*U. S. Dept. Agr., Bur. Plant Indus. Bul.* 245, pp. 100, pls. 10, figs. 10).—This paper embodies the main facts in the development of the disease and of methods for its control by spraying and other standard practices, and also contributes a number of new facts as to the development of resting spores by the fungus. The work was begun and carried on to a considerable extent at the Vermont Station in cooperation with the Bureau of Plant Industry.

The potato disease termed the late blight and rot due to *P. infestans* is one of the most serious of all potato diseases in Europe and America. It is common in the northeastern States, being favored by rather cool, moist summers, but farther south and west it is less common and probably only occurs when introduced with seed from the North. It does not persist where late summers are warm and dry.

The disease does not attack the leaves, as a rule, until after the blossoming period. The fungus develops first on the foliage, from which it passes by means of spores that are washed into the soil to the tubers, in which it hibernates.

Studies of infection, transmission, and disease control have shown that tuber infection in the field may be prevented by spraying the soil even when the fungus is allowed to develop unchecked on the foliage. Tubers may be infected from contact with blighting foliage at digging time. Secondary infection of tubers may occur in the soil or in the storage bin.

When the tops are attacked by late blight the harvesting of the tubers should be delayed for some time after the death of the tops. Dry, cool storage is of primary importance to prevent the spread of the disease in bins, and the use of lime or formalin disinfection has proved valueless. Wind and water are considered the most important agencies in local spore distribution, although leaf-eating insects may carry the spores to some extent.

The method described by Jensen of covering the tubers to a depth of 4 to 5 in. was found valuable in preventing infection through the soil, and disinfecting tubers designed for seed purposes by exposure to dry heat, 40° C. for 4 hours, was also demonstrated to be of value in preventing the infection of the disease. The results of 20 years' spraying experiments at the Vermont Station have shown that spraying the foliage with Bordeaux mixture is an almost complete remedy against both the blight and the rot, and also operates beneficially to the potato plant in other ways (*E. S. R.*, 26, p. 53).

The fungus causing this disease has been carried in pure culture since 1904 and a considerable number of facts determined relating to its life history. Strains have been grown continuously for more than 5 years without any evidence of change in pathogenicity or other characters. The limits of alkalinity, acidity, temperature, etc., for growth and spore formation have been deter-

mined. Bodies having the characters of thick-walled spiny resting spores have been produced that had the general appearance and cytological characters of oogonia, but no antheridia have been found. A search for these bodies in cultures on blocks cut from potato tubers revealed immature stages of what were considered the same bodies, but none has been found in decaying tubers following *Phytophthora* attacks. Somewhat similar bodies have been found in leaves killed by the fungus, but as yet the authors do not claim that resting spores occur in nature.

In connection with their investigations some varieties of potatoes have been found much more susceptible to disease than others, and a method of determining disease resistance, which consists of inoculating sterile blocks cut from the flesh of potato tubers with *Phytophthora* cultures, has given results that are fairly comparable with those obtained in the field. This method of judging rot resistant qualities is believed worthy of extended application. In general certain standard European varieties were found more highly resistant to the fungus than the standard American varieties. In attempting to determine the cause of resistance no definite information was found, but it apparently does not consist in differences in the relative acidity or in any other chemical factor that has been determined.

An extended bibliography is appended.

**Ustilagineæ on *Andropogon sorghum* in America**, A. A. POTTER (*Abstr. in Phytopathology*, 2 (1912), No. 2, p. 98).—In the course of an investigation on the smuts of America, the author reports having studied *Sphacelotheca reiliana*, *S. sorghi*, and *Ustilago cruenta*. The latter species has not been previously recognized in American literature.

**Notes on some plant diseases of the sugar cane in the Hawaiian Islands**, J. E. VAN DER STOK (*Arch. Suikerindus. Nederland. Indië*, 20 (1912), No. 18, pp. 609-631; *Meded. Proefstat. Java-Suikerindus.*, 1912, No. 17, pp. 529-551).—This article is the result of a visit of the author to the Hawaiian Islands in 1911, and gives accounts of a number of diseases of sugar cane, most of which have been previously described by Cobb (*E. S. R.*, 18, p. 843; 22, p. 49).

**Infection experiments with the powdery mildew of wheat**, G. M. REED (*Phytopathology*, 2 (1912), No. 2, pp. 81-87).—In a former paper (*E. S. R.*, 21, p. 641) the author showed that biological specialization has resulted in distinct forms or races of mildews on each of the principal cereals, oats, barley, rye, and wheat. Further studies have shown that different varieties vary in their susceptibility, and in the present paper an account is given of investigations to test the resistance of varieties of wheat to wheat mildew.

In all, 78 varieties of wheat, representing 9 different species of *Triticum*, were studied, the inoculation material in nearly every instance being conidia from the Turkey Red wheat. Forty-nine of the 78 varieties gave 100 per cent infection. Fifteen of the remaining ones gave an infection of 70 per cent or higher, while of the remaining 14 varieties, 4 were infected to the extent of from 50 to 70 per cent, 6 gave only slight infection, and 4 were immune.

The greater number of varieties of *T. vulgare* were found susceptible to mildew, while the immune varieties belonged to the species *T. dicoccum* and *T. vulgare*. The varieties of the different species which showed a marked resistance to mildew were all spring varieties. In some cases where the same variety was grown as a winter and spring wheat, the winter variety was susceptible while the corresponding spring variety was relatively or entirely immune.

There was no evidence to indicate a specialization of wheat mildew within the genus on its various hosts.

In conclusion the author calls attention to the fact that the immunity which a host plant enjoys from mildew may be due largely to environmental conditions. From a large number of experiments he has carried on he has reached the conclusion that water supply, nutrition, relative abundance of spores, etc., play an important part in the susceptibility or immunity of a particular plant to fungus parasites.

**Notes on some apple diseases, F. A. WOLF** (*Proc. Ala. State Hort. Soc.*, 9 (1912), pp. 69-75).—Popular descriptions and methods for control of the bitter rot and rust of apples are given.

**Canker diseases of apple trees, PROBST** (*Gartenwelt*, 16 (1912), No. 21, pp. 284-286).—The author discusses the difference in susceptibility of different varieties of apple trees to canker, due to *Nectria cinnabarina*, and the relation of the fungus to frost and other injuries of the trees.

The fungus is considered a wound parasite. The cankers are said to be more liable to appear on trees in poor dry soils and in soils in which the water table is near the surface. Planting in such situations should be avoided, and especially susceptible varieties should not be employed in setting orchards. Where cankers are found upon the trees they should be carefully cut out from the trunks and larger limbs and the wounds covered with coal tar. When on smaller branches the whole branch should be cut off and burned.

**Two apple cankers, H. S. FAWCETT** (*Mo. Bul. Com. Hort. Cal.*, 1 (1912), No. 7, pp. 247-249, figs. 2).—Descriptions are given of 2 forms of apple canker, due to *Nectria ditissima* and *N. cinnabarina*.

**Apple scab infection as correlated with maturity of ascospores, weather conditions, and development of fruit buds, E. WALLACE** (*Abs. in Phytopathology*, 2 (1912), No. 2, pp. 94, 95).—From observations covering a period of 3 years in New York it is concluded that if the weather conditions are favorable the primary spring infection usually occurs about the time the ascospores mature, that is, usually about the time the apple blossoms are ready to open. There is believed to be little probability of serious infection earlier than this, whatever the weather conditions may be. Later secondary infections were studied, and the date of attack and relation of rain to infection were determined.

**Frost injuries to apples, A. NAUMANN** (*Reprint from Ztschr. Obst u. Gartenbau* [1911], No. 2, pp. 4, figs. 2).—This is a brief discussion with illustrations of conditions observed to follow low temperatures on young fruits, including invasions by fungi, etc., favored by such injuries.

**Gum diseases in citrus trees, H. S. FAWCETT** (*Mo. Bul. Com. Hort. Cal.*, 1 (1912), No. 5, pp. 147-156, figs. 5).—Descriptions are given of a number of diseases of citrus trees in California, and comparisons made with similar diseases in Florida. The diseases described are gummosis or lemon gum disease; scaly bark of California, which is said to be the same as psorosis in Florida; foot rot or mal di gomma, which is common in Florida and rare in California; root rot, due to some of the higher fungi; and *Diplodia* gumming and Florida scaly bark, both of which are present in Florida but thus far have not been reported in California.

**A new species of Pyrenomycetes, N. NAUMOW** (*Bul. Trimest. Soc. Mycol. France*, 28 (1912), No. 1, pp. 55, 56, fig. 1).—A description is given of a new fungus, *Pleospora batumensis* n. sp., which was found attacking the petioles of orange leaves in the south of Russia.

**The treatment of downy mildew, black rot, and powdery mildew, J. LEROU** (*Rev. Vit.*, 37 (1912), No. 957, pp. 526-528).—The author describes methods for combating the above diseases that have been repeatedly tested with success by growers.

For the downy mildew 3 treatments with liquid fungicides followed by 2 with powdered sulphates, for the black rot 4 treatments with liquid fungicides and 2 with powdered sulphates, and for the powdery mildew 2 treatments with pure sulphur combined with the necessary complementary treatments with powdered sulphates are said to be sufficient for the control of these diseases. The time for the different applications will vary with atmospheric and other conditions. The liquid fungicides recommended are Bordeaux mixture, Burgundy mixture, Bordeaux mixture to which molasses is added to improve its adhesiveness, and copper acetate solutions, formulas for the preparation of which are given. In choosing the powders there is said to be but little difference, except that the first-named should contain at least 50 per cent sulphur.

**Infection of the grape by downy mildew**, L. RAVAZ and G. VERGE (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 19, pp. 581-584).—In continuation of previous work (E. S. R., 27, p. 49), the authors investigated the susceptibility of flowers, fruits, pedicels, peduncles, and shoots of several varieties of grape to mildew attack. They conclude from these that the fruit stems are less open to infection than are the leaves, that the flowers are most liable to attack, and that the berries were not contaminated in any case. Density of tissue and rarity of stomata are supposed to be in a measure protective in this connection.

**The influence of weather on Peronospora disease of grape**, R. GERNECK (*Weinbau u. Weinhandel*, 30 (1912), No. 18, pp. 199, 200).—A short discussion is given of the conditions favoring attacks by this disease as illustrated by observations of recent years. Such conditions are said to be heavy rainfall, heat, and shade. Storms furnish all these conditions at once, and have been followed by notable outbreaks.

**A new parasite of the grape**, L. PLANCHON (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 22, pp. 676-686, pl. 1, figs. 7).—A description is given of *Osyris alba*, a phanerogamic plant which is reported growing as a parasite or hemiparasite on the roots of grapes in parts of France.

**A mulberry disease**, R. AVERNA-SACCÀ (*Bol. Agr. [São Paulo]*, 12, ser., 1911, No. 9-10, pp. 727-740, figs. 3).—An account is given of the symptoms and spread of a leaf spot disease which is ascribed by the author to *Sphaerella moricola* and is said to have been confused with that due to other organisms, as in case of mulberry bacteriosis. A discussion is given of allied fungi, of conditions favorable to spread of this disease, of varieties of mulberry found to be resistant thereto, and of preventive or remedial measures, as sulphate of copper and Bordeaux mixture. A brief bibliography is appended.

**Further studies on the pecan rust**, F. V. RAND (*Abs. in Science, n. ser.*, 35 (1912), No. 913, p. 1004).—In a preliminary report (E. S. R., 26, p. 53) the author described the fungus causing the leaf disease of pecans as *Mycosphaerella convexula*. Since that time additional studies have been made, and in the course of 1½ years' growth in cultures strains originally producing a majority of apparently two-celled ascospores have changed until now most of the ascospores are distinctly nonseptate. Furthermore, a typical *Glæosporium* form has developed in culture and has also been obtained from the host. Inoculations with cultures which originated from single ascospores made on Jonathan and Yellow Newton apples gave a decay similar to the bitter rot, with the production of conidia and immature perithecia on the latter.

From the studies thus far made it appears that the fungus is closely related if not identical with *Glomerella rufomaculans*, and that it is not a very active parasite on the pecan.

**A bacterial disease of Aster chinensis**, G. L. PAVARINO (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5, ser., 21 (1912), I, No. 8, pp. 544-546).—The author describes a disease of asters due to *Bacillus asteraccarum* n. sp.

The leaves seem to be first attacked, and the disease spreads from the lower to the upper part of the plant, discoloring the leaves, which finally become brown and dried. A technical description of the organism is given.

Notes on winterkilling of forest trees, C. P. HARTLEY (*Forest Club Ann. [Univ. Nabr.]*, 4 (1912), pp. 39-50).—The author gives an account of observations made in District 2 of the United States Forest Service of injuries to trees, the different types of which are grouped under the general term of winterkilling. Particular attention is paid to the injury which occurred in the Black Hills Forest in 1909 during one of the chinook periods, or at the time when an unusual rise in temperature was followed by a very sudden and decided fall.

A new leaf disease of the white alder, F. W. NEGER (*Naturw. Ztschr. Forst u. Landw.*, 10 (1912), No. 6, pp. 345-350, figs. 2).—An account is given of a leaf spot disease of *Alnus incana* in Norway. The fungus causing it does not seem to be identical with any known species, and it is provisionally described as *Guomoniella albomaculans* n. sp.

The chestnut bark disease, W. H. RANKIN (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 99).—A study of specimens of the mature perithecial stage of the fungus showed the perithecia dehiscing under moist conditions throughout the summer. The conidial stage of the fungus, differing from the usual pycnidia, was found commonly developing on the wood. The sap wood was said to be markedly affected and the leaves killed through a toxic effect. The author claims there is evidence that the relative water and air content of the tree determines its susceptibility to the fungus.

The oak mildew, E. GRIFFON and A. MAUBLANC (*Bul. Trimest. Soc. Mycol. France*, 28 (1912), No. 1, pp. 88-104, pls. 3).—The results are given of a series of investigations on the different powdery mildews occurring on the oak, the authors concluding that the American species of *Microsphaera* on the oak are *M. abbreviata* and *M. extensa*, and that they are both distinct from *M. alni* of Europe. The species occurring on the oak in Europe is said not to be identical with any of the American species, but is probably an introduced one of unknown origin, and the authors propose for it the name *M. alphitoides*.

The Hendersonia disease of *Eucalyptus globulus*, A. R. DAVIS (*Pomona Col. Jour. Econ. Bot.*, 2 (1912), No. 1, pp. 249-251, figs. 2).—The author describes *H. eucalypticola*, an apparently undescribed species occurring on the leaves of eucalyptus in southern California. The fungus was apparently distributed over quite an area, but the actual damage being done by it at present seems to be slight. Its attacks seemed to be confined exclusively to the young broad leaves, the slender longer leaves being, so far as the author has observed, immune to attack.

Two fungus diseases of coniferous trees, J. FISHER (*Agr. Jour. Union So. Africa*, 3 (1912), No. 3, pp. 389-391, figs. 2).—Two leaf cast diseases are reported at the Central Experiment Farm, Natal as killing terminal and lateral shoots and in some instances trees. One of these diseases said to be due to *Diplodia pinca*, is supposed to be confined to the genus *Pinus*. The other, ascribed to *Pestalozzia funcrea*, is reported on *Pinus pinaster*, *P. canariensis*, *P. longifolia*, *P. insignis*, *P. massoniana*, *Cupressus lusitanica*, *C. lawsoniana*, *Casuarina leptoclada* and possibly on *Callitris australis*. Wounds made by hail or in handling and wet weather favor the development of the disease. Protective measures suggested include removal and burning of infected or suspected parts, avoidance of diseased ground in planting susceptible trees, and care in selecting nursery stock and handling young trees.

The superficial tension and wetting power of insecticides and fungicides, and means for increasing their wetting power, V. VERMOREL and E. DANTONY (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 20, pp. 1300-1302; reprint,

pp. 4; *Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 20, pp. 613-615; *Jour. Agr. Prat., n. ser.*, 23 (1912), No. 21, pp. 665, 666).—The authors have studied various means of augmenting the efficiency of fungicides and insecticides by increasing their wetting power. Saponin, soap, castor oil, and gelatin were added to the mixtures, and their covering power determined.

The authors conclude that the wetting power of the solution, so far as it relates to plants, depends upon the facility with which the solution forms liquid films and the resistance of these films to superficial tension. The determined wetting power of a solution for one plant or plant organ does not necessarily imply that it will have the same ability to wet other bodies or other organs.

In the authors' experiments the best results were obtained with gelatin added at the rate of from 10 to 50 gm. per hectoliter of fungicide. This proved much better and cheaper than any of the other substances tested. All forms of gelatin are thought not equally desirable, especially when used with Bordeaux mixture and Burgundy mixture. This matter is to be given further study.

A modified copper acetate fungicide is recommended, made by the following formula: Water 100 liters, neutral copper acetate 1 kg., and gelatin from 10 to 20 gm. The copper acetate is dissolved in 100 liters of water, and the gelatin is dissolved in hot water, after which the solution containing the gelatin is poured into the copper solution, thoroughly stirred, and applied.

In the reprint it is claimed that practically all forms of gelatin are equally adapted to use in connection with the above formula.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

**Report of an expedition to Laysan Island in 1911, under the joint auspices of the United States Department of Agriculture and the University of Iowa** (*U. S. Dept. Agr., Bur. Biol. Survey Bul.* 42, pp. 30, pls. 9, fig. 1).—This report consists of 2 parts.

*Report on conditions on the Hawaiian bird reservation with list of the birds found on Laysan*, H. R. DILL (pp. 7-23).—This is a report of an expedition sent to Laysan, the largest and most important island of the Hawaiian Islands Reservation, to ascertain the present condition of the bird rookeries and to collect a series of birds for a museum exhibit. A period of about 2 months during April, May, and June was spent upon the island. A brief description is first given of the Hawaiian Islands Reservation, with notes on seals, introduced rabbits and guinea pigs, insect pests, and birds as seed carriers. Then follows a brief narrative of the expedition and an extended annotated list of birds of Laysan, together with an island bird census.

*Report on conditions on Laysan, with recommendations for protecting the Hawaiian Islands Reservation*, W. A. BRYAN (pp. 24-30).—This report consists of a comparison of conditions in 1903 and 1911 and recommendations for the future protection of the reservation.

**Our mid-Pacific bird reservation**, H. W. HENSHAW (*U. S. Dept. Agr. Year-book 1911*, pp. 155-164, pls. 2, figs. 2).—This paper is largely based on the above noted bulletin.

**Handbook of birds of eastern North America**, F. M. CHAPMAN (*New York and London, 1912, rev. ed.*, pp. XXI+530, pls. 24, figs. 136).—Much of this revised edition is said to have been rewritten. The nomenclature is that of the 1910 edition of the A. O. U. Check List.

**Michigan bird life**, W. B. BARROWS (*Michigan Agr. Col. Spec. Bul.*, 1912, pp. XIV+822, pls. 70, figs. 152).—A list of all the birds (336 species and subspecies) known to occur in Michigan, together with an account of the life history of each species and special reference to its relation to agriculture.

A hypothetical list, which includes species that have been attributed to Michigan but whose status is doubtful; a list of books, papers, and short notes relating mainly or entirely to Michigan birds; a glossary of the technical terms used in keys and descriptions; an outline of classification of North American birds; and a list of contributors, are presented in appendices.

**Hungarian partridge and pheasants in Missouri**, J. A. TOLERTON (*Dept. Game and Fish [Missouri], Bul. 1, 1911, pp. 100, pls. 2*).—This bulletin consists largely of reports received from correspondents relating to the experimental raising of Chinese pheasants and Hungarian partridges in Missouri.

**Studies in bird migration**, W. E. CLARKE (*London, 1912, vols. 1, pp. XVI+323, pls. 9; 2, pp. VII+346, pls. 16, fig. 1*).—These studies are said to be the results of many years' personal observations and researches, during which exceptional opportunities for acquiring special knowledge of the subject were afforded the author.

**The food of birds**, LAURA FLORENCE (*Trans. Highland and Agr. Soc. Scot., 5. ser., 24 (1912), pp. 180-219*).—In this paper the author presents details of a year's investigations of the food of 616 birds, representing 73 species. The majority of the birds examined were shot while feeding on agricultural land, and the specimens were obtained chiefly in the northeastern counties of Scotland, although a small number sent from the southern counties and England have been included.

"During a week of severe frost in February (1910) a number of starlings were examined, and in almost every case the food consisted of corn, seeds, and fruits of weeds and wild plants. All the seeds, with the exception of the corn, were found in every part of the intestine in perfect condition, consequently providing no sustenance for the birds, who were thus acting as distributors of the seeds."

**Bird protection with particular consideration of the insect eating birds**, G. RÖRIG (*Flugschr. Deut. Landw. Gesell., 1910, No. 11, pp. 46, figs. 15*).—This paper deals largely with the practical methods of fostering and protecting beneficial birds.

**Notes on the bionomics of rats and ground squirrels**, G. W. MCCOY (*Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Rpts., 27 (1912), No. 27, pp. 1068-1072*).—The notes here presented are based on observations made in connection with the eradication work conducted in California. They relate to breeding and raising in captivity, life in captivity, breeding seasons, foods, and the starvation of rats.

**Comparative investigations of the action of bacterial and chemical rat destroying preparations**, AUMANN (*Centbl. Bakt. [etc.], 1. Abt., Orig., 63 (1912), No. 2-3, pp. 212-221, figs. 2*).—In observations and experiments extending from 1905 to 1910 in which 30 preparations were employed, the best results followed the use of phosphorus (from 96 to 100 per cent mortality) and squill (from 60 to 75 per cent mortality) preparations. With bacterial preparations only unsatisfactory results (20 to 33½ per cent mortality) were obtained.

**The rat guard used in the Philippine Islands**, C. FOX (*Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Rpts., 27 (1912), No. 23, pp. 907, 908, figs. 2*).—A rat guard for ships' lines is described and illustrated.

**Crawfish as crop destroyers**, A. K. FISHER (*U. S. Dept. Agr. Yearbook 1911, pp. 321-324, pl. 1*).—Although crawfish have heretofore been generally supposed to be of little agricultural importance, it has been found that in the Houston clay lands in Mississippi and Alabama, there are areas estimated at not less than 1,000 square miles infested by crawfish on which it is almost impossible to raise any crops with profit. The formation they inhabit is a

heavy gumbo soil from 4 to 15 ft. in depth, well saturated with water, and overlying a sandstone formation.

The crawfish "do the greatest amount of damage just after the plant appears and before secondary leaves are developed. Large fields of young cotton have been destroyed in a single night. Corn also is extensively eaten, but is not so badly damaged as cotton." It is stated that in badly infested areas there are from 8,000 to 12,000 holes to the acre; on one plantation 27 bbls. of crawfish were picked up in a season, and the following year 13 bbls. more were secured.

Very little is known regarding the breeding habits of this injurious species. "The number of young is variable, but usually increases with the age of the mother, so that females which at first have only from 50 to 100 eggs, may later in life produce 400 eggs or more at a time. The development of the eggs requires about a month, and the young remain with their mother for from one to two weeks before starting an independent life. They grow rapidly during the first summer, molting about once a month, until they attain in fall, or beginning of cold weather, a length of approximately 2 in. Crawfish are solitary in habits, and 2 are rarely found in one burrow, except during the mating season or when females are accompanied by young."

Repressive measures include deep tile draining, the collection and crushing of crawfish, and the use of poison. In experiments with carbon bisulphid, chlorid of lime, and calcium carbid, it was found that carbon bisulphid gives the best results. The most practical and economical means of coping with the crawfish problem is to kill as many as possible by mechanical means before seeding, and to treat the remaining occupied burrows with poison, preferably carbon bisulphid.

**Handbook of pathogenic protozoa**, edited by S. VON PROWAZEK (*Handbuch der Pathogenen Protozoen. Leipzig, 1912, pt. 4, pp. 361-515+VII, pls. 7, figs. 36*).—In this fourth part, which completes volume 1. *Treponema pallidum* is dealt with by P. Mühlens (pp. 361-486); and The Gregarines, by C. Schellack (pp. 487-515). Bibliographic lists accompany both papers.

**Bibliography of Canadian zoology for 1910**, L. M. LAMBE (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 5 (1911), Sect. IV, pp. 155-163*).—Eighty-two titles are listed in this bibliography.

**Bibliography of Canadian entomology for the year 1910**, C. J. S. BETHUNE (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 5 (1911), Sect. IV, pp. 165-176*).—One hundred and sixteen titles are listed in this bibliography.

**The entomological code: A code of nomenclature for use in entomology** (*Washington, D. C., 1912, pp. 31*).—The code here presented was compiled by N. Banks and A. N. Caudell for the purpose of aiding entomologists in deciding questions of nomenclature arising in their work. In its preparation, the various codes of nomenclature were frequently consulted and used, various published articles on nomenclature were referred to, and a preliminary draft was submitted to many of the principal systematic entomologists of America, and their opinions given consideration. It is pointed out that existing codes fail to cover many points which continually arise in entomological work, or the language used is of such a broad or indefinite scope as to require official interpretation to make the meaning evident; that scarcely an entomologist has been connected with the preparation of the larger codes; and that the codes prepared by entomologists have been of restricted scope or made with certain questions in view.

**A manual of injurious insects**, W. B. COLLINGE (*Birmingham, Eng., 1912, pp. XX+268, figs. 105*).—This work has been prepared with a view to directing the attention of farmers, fruit growers, horticulturists, and others to the life

histories of a few of the commoner injurious insects, and to the importance of a full appreciation of the methods of controlling them, particularly so as regards cultural methods. It is stated that the life history of nearly every insect mentioned has been carefully worked out by the author and that the text is largely compiled from his writings or is based on observations made during an experience of many years. Instructions for using hydrocyanic-acid gas and bisulphid of carbon, an account of the black-currant gall-mite, and a list of plants with injurious insects are presented in appendices.

**The brains of insects**, H. E. ZIEGLER (*Naturw. Wechschr.*, 27 (1912), No. 28, pp. 433-442, figs. 18).—An illustrated account of studies of the brains of insects.

**Report of the state entomologist**, T. B. SYMONS (*Rpt. Md. State Hort. Soc.*, 13 (1910), pp. 96-112).—This report includes brief statements of the work of the year 1910, including inspection of imported trees and plants, work with the terrapin scale (E. S. R., 24, p. 658), orchard inspection, San José scale, nursery inspection, public spraying, etc.

**Report of the state entomologist**, T. B. SYMONS (*Rpt. Md. State Hort. Soc.*, 14 (1911), pp. 165-174).—A brief statement is given of the work of the year 1911, including nursery inspection, experimental work, public spraying demonstration, etc.

**Insect pests of the Lesser Antilles**, H. A. BALLOU (*Imp. Dept. Agr. West Indies Pamphlet 71, 1912, pp. IX+210, figs. 185*).—As the author states, the object of this handbook is to present in plain and simple language a brief general account of the present knowledge of some of the principal insect and mite pests of the crops grown in the Lesser Antilles, also of the pests attacking man and domestic animals, and those of the household.

**Annual report for 1911 of the zoologist**, C. WAREURTON (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 381-387).—A brief report is given of the occurrence during the year of insect enemies of forest trees, corn, grass, general farm and garden crops, and fruit.

**Insect pests in 1911**, R. S. MACDOUGALL (*Trans. Highland and Agr. Soc. Scot.*, 5, ser., 24 (1912), pp. 120-138, figs. 6).—The insects here considered include the large larch sawfly (*Nematus crichsoni*); *Strophosomus coryli*, a weevil which at times injures young conifers, etc.; a tineid (*Ecophora sulphurella*) attacking beech and oak; *Pemphigus bursarius*, which forms galls on the leaf stalks of poplar; the common rustic moth, *Apamea (Hadena) didyma (oculca)*, which attacks grain crops; the chrysanthemum leaf mining fly (*Phytomyza geniculata (horlicola)*); the brown spotted pinion (*Orthosia litura*), found feeding on the leaves of cereals; and 2 dipterous enemies of cereals, namely, the frit fly (*Oscinis frit*) and the wheat bulb fly (*Hylemyia coarctata*).

**Report of the entomologist and vegetable pathologist**, H. TRYON (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1910-11, pp. 70-79*).—This report includes a brief account of the occurrence of insect pests, ticks, etc., and the work therewith during the year 1910-11.

**Report of the entomological branch**, L. J. NEWMAN (*Dept. Agr. and Indus. West. Aust. Ann. Rpt. 1911, pp. 29-31*).—This report consists of accounts of the occurrence of the more important insect enemies of the year.

**Papers on cereal and forage insects** (*U. S. Dept. Agr., Bur. Ent. Bul. 95, pt. 6, pp. 98-108, pl. 1, figs. 17*).—This part consists of 2 papers.

**The legume pod moth** (*Etiella zinckenella schisticolor*), J. A. Hyslop (pp. 89-104).—The first mention of the legume pod moth as of economic importance in the United States was found by the author in unpublished notes of T. Pergande in the files of the Bureau of Entomology and refers to injury caused to Lima bean pods collected by A. Koebele in Eldorado County, Cal. in July, 1885. Since that time it has been recorded as feeding on the seeds of several species of leguminous plants, including the common rattlebox (*Crotalaria sagittalis*), at

Stillwater, Okla., *C. incana* at Coconut Grove, Fla., and the seed pods of milk vetch (*Astragalus* sp.). The author has reared the species from pods of the common lupines (*Lupinus* spp.) and Canada field peas at Pullman, Wash.

Technical descriptions given of the stages are followed by accounts of its seasonal history and of field work. A newly emerged larva was first found by the author at Pullman, Wash., on July 26, 1911. The larvæ feed for about 3 weeks, only partly consuming the peas, but destroying them as seed and greatly reducing their weight as stock feed. The pod always contains a mass of frass held together by a loosely constructed web. When mature, if the peas are still unharvested in the field, the larva emerges from the pods and enters the ground to pupate, or if the pods have been harvested it spins a tough silken cocoon in the nearest available sheltered place.

"Larvæ that become mature during the warm weather of early August, out of doors, or later under laboratory conditions, pupate immediately and emerge as adults in about 6 weeks. Adults have been obtained in our laboratory on August 5 and as late as August 28. Whether these lay eggs which pass the winter successfully, or whether they hibernate as adults, is still undetermined. Larvæ that reach maturity in late September, when the nights are cold, spin their cocoons and hibernate therein as larvæ, pupating in the spring and emerging at the time the earliest lupines are setting seed.

"On the lupines there are very probably 2 generations a year. The moths of the first generation, coming from hibernating larvæ, lay all their eggs on the lupines, as the field peas are just commencing to grow. The offspring of this generation mature late in July and, finding the field peas ripening, very naturally turn their attention to these large areas of suitable food as well as to their natural food, the later lupines." In investigations made in 1910 of more than 100 varieties of field peas at Pullman, Wash., it was found that the varieties which began blooming during and after the last week in June were decidedly the most severely attacked. In investigations of 67 varieties in 1911 it was found that those in full bloom prior to June 28 were practically unmolested.

The author's observations indicate that this insect can very easily be introduced into regions where it does not at present occur by being shipped with the seed field peas, it having been found in sacks of seed peas.

Two hymenopterous parasites were reared from the larvæ at Pullman, Wash., namely, *Pseudapanteles etiellæ* and *Microbracon hystopi*. Two other species are recorded as having been reared.

"The legume pod moth is readily controlled by preventive measures. . . . The transportation of the hibernating forms in sacks of seed, and the consequent dissemination of the pest, may be prevented by fumigation of the seed with carbon bisulphid. Owing to the presence of the native lupines, extermination of the pest is impossible, but by planting such early varieties of field peas as come into full-bloom before the last week in June it may be practically eliminated as a factor to be dealt with in seed growing in the Pacific Northwest. The date of planting, however, will vary in different localities and under different conditions."

*The legume pod maggot* (*Pegomya planipalpis*), J. A. Hyslop (pp. 105-108).—In investigations of 1910 it was found that *P. planipalpis* is quite capable of independently infesting seed pods and that it is actually a seed destroyer. Many pods were found to contain from 1 to 3 of its larvæ. This insect has been previously reported as attacking radishes at San Francisco, Cal. In cages with earth in the bottom the pupæ were always to be found below the surface at distances ranging from 1 to 3 in. Technical descriptions are given of its stages.

Two chalcidid parasites, *Holaspis* n. sp. and an undetermined form, have been reared from the legume pod maggot. This maggot has not as yet become a

serious factor in field-pea seed growing in the Pacific Northwest. "The dissemination as hibernating puparia can be readily prevented by fumigation. As is the case with the legume pod moth, it can not be exterminated because of the native lupines.

**Some insect pests of maize**, R. W. JACK (*Rhodesia Agr. Jour.*, 9 (1912), No. 5, pp. 707-716, pls. 4).—A brief account is given of the injury caused by some of the more important insect enemies of corn in Rhodesia.

[**The cotton worm and the Mexican cotton boll weevil**], W. E. HINDS (*Alabama Col. Sta. Rpt. 1911*, pp. 22-24).—Careful examinations made in the field showed that the cotton worm actually decreased the Alabama cotton crop of 1911 by approximately 10 per cent.

"The advance of the boll weevil began during the latter part of August, 1911, and continued until about the middle of November when frost killed the cotton. The infested area then included all or part of 12 counties in Alabama, the weevil line extending in a general southeasterly direction from near the northeast of Pickens County to the middle of Escambia County. . . . The area now infested by the weevil should produce about 10 per cent of the normal Alabama crop."

**Relation between rotation systems and insect injury in the South**, W. D. HUNTER (*U. S. Dept. Agr. Yearbook 1911*, pp. 201-210).—This article points out some of the general considerations that must be taken into account in connection with rotation practices which are coming to be generally followed in the southern United States. Examples are given of simple means of reducing insect injury by modifications of rotation systems.

**Pests and diseases**, W. N. SANDS (*Imp. Dept. Agr. West Indies, Rpts. Bot. Sta. [ctd.]*, St. Vincent, 1910-11, pp. 14, 15).—A brief report is given of the occurrence during the year of some of the more important insect enemies of cotton.

**Parasites of insects attacking sugar cane**, R. C. L. PERKINS (*Hawaiian Sugar Planters' Sta. Ent. Bul. 10*, pp. 5-27).—In this bulletin the author describes 19 new species and 1 new variety of chalcidoid parasites, nearly all of which were bred from eggs of insects attacking cane in countries other than the Hawaiian Islands. The American species were obtained by Koebele while investigating insects in the cane fields in Mexico during the winter months of 1908. All the rest were obtained by Muir in Fiji, China, and the Malay Islands. Three genera, namely, *Neotetrastichus*, *Jassidophthora*, and *Eomymar*, are characterized for the first time.

**Elm-leaf beetle and white-marked tussock moth**, E. P. FELT (*N. Y. State Ed. Dept. Bul. 511*, 1912, pp. 35, pls. 8).—This bulletin, which is a revision of New York State Museum Bulletin 109, previously noted (*E. S. R.*, 19, p. 355), presents popular accounts of these 2 shade-tree enemies.

**Forest entomology**, A. T. GILLANDERS (*Edinburgh and London, 1912*, 2. ed., pp. XXIV+428, figs. 354).—In this second edition (*E. S. R.*, 20, p. 652) the chapters have been rearranged more in accordance with the sequence of entomological classification.

**Insect damage to mine props and methods of preventing the injury**, T. E. SNYDER (*U. S. Dept. Agr., Bur. Ent. Circ. 156*, pp. 4).—This circular, based on special investigations in cooperation with mining companies, gives preliminary information on the principal types of insect injury and shows how a large percentage of injury can be prevented.

"By barking and seasoning mine timbers, insect injury before placement will not only be prevented, but injury by termites after placement will also be delayed or under some conditions even prevented and the length of life of the

timbers prolonged. . . . Impregnating props intended for permanent service with creosote by some standard process (either by the 'open-tank' or by the cylinder-pressure processes) will keep out termites and other wood-boring insects and preserve the props for a much longer period than they would last untreated."

See also previous notes (E. S. R., 24, p. 256; 27, p. 443).

A contribution to the study of the lucifuge termite, J. FEYTAUD (*Arch. Anat. Micros.*, 13 (1912), No. 4, pp. 481-607, pls. 3, figs. 34).—This paper deals with the anatomy and histology of, and the foundation of new colonies by, *Leucotermes (Termes) lucifugus*. A bibliography is appended.

The greenhouse thrips (*Heliotrips hæmorrhoidalis*), H. M. RUSSELL (*U. S. Dept. Agr., Bur. Ent. Circ. 151*, pp. 9, figs. 7).—This circular is based on the paper previously noted (E. S. R., 21, p. 559).

Spraying for the orange thrips, A. W. MORRILL (*Arizona Sta. Rpt. 1911*, pp. 552-554).—It was found that lime-sulphur solution alone, at the rate of 1 part to 85 parts of water, was as effective as when tobacco extract was added.

Note on a trypanosome from *Conorhinus rubrofasciatus* and its inoculation into the rat and mouse, A. LAFONT (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 9, pp. 380-382; *abs. in Sleeping Sickness Bur. [London], Bul.*, 4 (1912), No. 36, pp. 140, 141).—Flagellates were found by the author in the alimentary tract of 80 per cent of the reduviid *C. rubrofasciatus* captured in the island of Mauritius and of 50 per cent of those taken in the island of Réunion. A series of forms between leptomonas and trypanosome types was found, the first named being rare. The name *Trypanosoma boylei* has been given to the trypanosome form, inoculation experiments with which are briefly reported. The author points to the possible pathogenic rôle of this trypanosome for man.

Elm-leaf curl and woolly aphid of the apple, EDITH M. PATCH (*Science, n. ser.*, 36 (1912), No. 914, pp. 30, 31).—Spring migrants of *Schizoneura americana*, which causes the elm-leaf curl, having been observed to desert the elm leaves in the early summer, and fall migrants of *S. lanigera* (the woolly aphid of the apple) to leave the apple branches in the fall, the author conducted investigations to determine a possible relationship.

In the spring of 1912 elm-leaf curl was obtained from the South and the emerging winged forms were caged over apple seedlings in the greenhouse while depositing their young. "As a result, the progeny, a fine lot of nymphs that are growing along creases where the thin bark is scaling back, in the axils of the leaves, and on exposed roots of the apple seedlings, covered by a typical flocculent white secretion, would be pronounced 'woolly aphid of the apple' by any nursery inspector." It is pointed out that if the American species on elm is the same as the European species, the name of our orchard pest, the woolly aphid, will revert to *S. ulmi*.

Papers on deciduous fruit insects and insecticides.—The grape scale (*Aspidiotus [Diaspidiotus] uvæ*), J. F. ZIMMER (*U. S. Dept. Agr., Bur. Ent. Bul. 97*, pt. 7, pp. 115-124, pls. 3, figs. 2).—The grape scale has been reported to be more or less destructive to grape vines during the last 3 decades. In addition to the grape it occurs to a very limited extent on certain forest and shade trees.

Notes of the Bureau of Entomology record the receipt of this scale from T. Pergande at St. Louis as early as 1875. It has since been found to be rather widely distributed in the eastern United States, occurring from Florida north to New Jersey. It is known to occur in Alabama, Arkansas, Delaware, District of Columbia, Florida, Georgia, Illinois, Indiana, Kansas, Kentucky, Maryland, Mississippi, Missouri, New Jersey, North Carolina, Ohio, Tennessee,

Virginia, and West Virginia, many parts of Europe, Brazil, Jamaica, and the West Indies.

It appears to have many habits similar to those of the San José scale. When abundant the grape scale very materially retards the development of the vines and always infests the second year's growth. The author's observations show the species to be viviparous with but a single brood each year. The female insect gives birth to from 35 to 50 living young during the months of May and June. After an active stage of about 2 days the young settle down on the cane and there is a fairly uniform development. Technical descriptions of the male and female and of their scales, prepared by E. R. Sasser, are presented.

In an examination made of female scales on May 20, 1911, the author found about 80 per cent to be parasitized, the parasites including *Ablerus elisiocampæ*, *Ablerus* n. sp., *Phycus varicornis*, *Phycus* sp., *Azotus marchali*, *Coccophagus* n. sp., and *Aphcltius fuscipennis*. *Controdora* sp., *Prospaltella murtfeldtii*, and *Stigmiphora pulchra* have also been reared by the author, and a mite of the genus *Tyroglyphus* has been recorded.

Lime-sulphur is recommended for winter use, but whale-oil soap solution, kerosene, or crude petroleum emulsion, etc., may be used. When it is desired to treat the grape scale during the period of foliage of the vines, the use of whale-oil soap at the rate of 1 lb. to 3 or 4 gal. of water, or of 10 to 12 per cent kerosene emulsion may be advisable. A second and sometimes a third application is said to be advisable on account of the habit of the young in settling under the shreds of dead bark.

A bibliography is appended.

**Diaspis pentagona in Argentina, J. M. HUERGO** (*Trab. J. Cong. Cient. Santiago de Chile*, 16 (1908-9), pp. 450-478, pls. 22).—This is a discussion of the occurrence, life history, natural enemies of and injuries caused by the West Indian peach scale in Argentina, with remedial measures therefor.

**Diaspis pentagona in the Province of Buenos Aires, T. AMADEO** (*Rev. Mens. Cám. Merc.*, 12 (1912), No. 117, pp. 27-35).—A brief account of the West Indian peach scale (*Aulacaspis* [*Diaspis*] *pentagona*), and remedial measures therefor.

**The cotton worm or cotton caterpillar (Alabama argillacea), W. D. HUNTER** (*U. S. Dept. Agr., Bur. Ent. Circ.* 153, pp. 10, fig. 1).—For 21 years prior to 1911 the cotton worm had not been generally abundant in the United States, although there was local damage of some severity during different years in that period. "The outbreak of 1911 did not originate in the United States, but in Central or South America. The moths flew northward very early in the season and reached the neighborhood of Brownsville, in Texas, by April. By the middle of June practically all of the cotton fields in the vicinity of Brownsville that had not been protected by the use of poisons had become defoliated. The new generations of the insects flew northward and eastward during June and July. During the latter month there appears also to have been another invasion of the United States from South America. This reinvasion took the moths into the South Atlantic States, where they were soon found in very great numbers. They bred with great rapidity and spread northward and westward. In August the western and eastern invasions coalesced, and within a few weeks the insects were numerous in cotton fields throughout the belt. . . .

"The cotton moth is of South American origin and does not survive the winters in the United States, except when the temperatures are above the normal or when individuals obtain unusual shelter." Whether there would be an outbreak in 1912 is thought to depend upon (1) the survival of the winter by moths in this country and (2) a new invasion from South America. In

careful searches for the moths made in favorable localities in the southern part of the cotton belt during the past winter and extending from Brownsville, Tex., to South Carolina, no live moths were found. Chrysalids of the moth placed in rearing cages at Victoria, Tex., in the fall of 1911 were all killed by cold by the end of January. Thus all the information obtainable led to the conclusion that an outbreak in 1912 would be dependent upon a reinvasion of the United States from some southern locality.

"For the control of the cotton worm the use of powdered arsenate of lead at the rate of 2 lbs. per acre is advised above all other means. This substance does not need to be mixed with any other material. Paris green, if used, should be mixed with lime and flour as described."

Descriptions of the stages of the cotton moth are included.

**The evergreen bagworm.** L. HASEMAN (*Missouri Sta. Bul.* 104, pp. 309-330, figs. 16).—The general distribution over the State, its wide selection of food plants, and the destructive nature of its work has led the author to consider the bagworm as probably the most troublesome insect pest attacking the foliage of trees in Missouri at the present time. While it has always been more or less destructive to evergreens, during the last few years it has become extremely destructive to many deciduous trees and shrubs and other plants. Large areas of bearing orchards are said to have been destroyed, seemingly by one defoliation. Although primarily a foliage pest, it has been known to feed upon developing fruit.

The original home of this native insect was in the South, where it is still most abundant. In its gradual northward spread, it has tended to follow river courses and the coast, this following of river courses being especially noticeable in its distribution in Missouri. "The pest is most abundant and destructive in the western half of the State, especially in the southwestern counties and along the courses of the Missouri and Osage rivers. In St. Joseph, Kansas City, and St. Louis it is extremely troublesome upon shade and ornamental trees. Throughout most of the northeastern and southeastern portions of the State it does little damage except in restricted regions. It is most abundant in cities and low bottom lands. In the cities its natural enemies are less numerous and the food supply is readily accessible, while in the bottom lands such food plants as willows grow in great profusion and the streams assist in its distribution. From the bottom lands it gradually migrates to the uplands, where it feeds largely upon ornamental, shade, and fruit trees." Over most of the area in which the bagworm is found, it appears in sudden outbreaks, being destructive for a year or two and then decreasing as its enemies gain the upper hand. In the orchard it is especially destructive to apple and plum, although it is found on the cherry, pear, quince, and peach. In the absence of its choice food plants, it will feed freely upon clover, ragweed, parsley, surge, and nightshade.

Studies made of its life history and habits are reported. The winter is passed in the egg stage inside the female bags. In the latitude of central Missouri the second week in May is the normal time for the first appearance of the larvæ outdoors. There is a great variation in the rate of its growth, it being not uncommon to find newly hatched, half-grown, and full-grown caterpillars on the same tree and frequently some caterpillars will be found full-grown before others of the same brood are half-grown. Although it has previously been reported to pass through 4 larval stages, the author's observations indicate that there are 5, the additional 1 coming soon after hatching. In observations of a colony the author found the first adult males to appear from August 15 to 20, and to be quite abundant and mating from September 5 to 12. Two weeks later the bags were found filled with eggs.

Three species of ichneumonids (*Pimpla inquisitor*, *P. conquisitor*, and *Allocota thyridopterigis*) are found commonly parasitizing the bagworm. The various small parasites reared from the bagworm from various parts of the State include *Habrocytus thyridopterigis*, which is most abundant; *Dibrachys boucheanus*, which is also common; and *Pteromalus* sp., *Tetrastichus* sp., and *Phobocles albinopennis*, which are less abundant. Limited observations led the author to consider ants an important check upon the young caterpillars. Birds were found to be important enemies.

Control measures consist (1) of the collection of the bags and (2) of the application of an arsenical. When collected all the female bags containing eggs should be placed in a box or barrel far from trees or shrubs, since this will render it impossible for the young caterpillars upon hatching to find their way to trees and at the same time prevent the destruction of beneficial parasites.

"As the result of experimental tests of the effect of poison upon bagworms of different ages, the writer finds that the very young caterpillars readily feed upon poisoned foliage and quickly succumb. The older caterpillars are more cautious about feeding upon sprayed foliage. From this it is evident that early spraying is desirable, for it not only proves more effective but also destroys the pest before the foliage is consumed. Arsenate of lead should be used, especially upon evergreens, since it sticks better and is less apt to burn the foliage. If the spraying can be done while the caterpillars are yet small, 2½ lbs. of arsenate of lead to 50 gal. of water is sufficient. When later spraying is done to control the older caterpillars it is advisable to use from 3 to 5 lbs. to 50 gal. of water, though at the latter strength slight burning may occur on evergreens. The first regular application of poison for the codling moth just after the blossoms fall will control the bagworm in orchards. One careful application of poison before the first of June will completely control the pest either upon fruit, evergreen, or shade trees."

The fostering and protection of birds is recommended.

**Butterfly hunting in many lands**, G. B. LONGSTAFF (*London, New York, Bombay, and Calcutta, 1912, pp. XVIII+728, pls. 16*).—This work deals with the occurrence, bionomics, etc., of various Lepidoptera and other insects, based upon observations made in Asia, Africa, New Zealand, Australia, North America, South America, and the West Indies. A series of papers by F. Müller dealing with the scent organs, etc., of Lepidoptera, translated from the German and Portuguese by E. A. Elliott, are presented in appendixes.

**The brown-tail moth in New Brunswick**, W. MCINTOSH (*Rpt. Agr. New Brunswick, 1911, pp. 232-236, pl. 1*).—A brief account is given of the work of combating in New Brunswick the brown-tail moth, an egg cluster of which was first found at Old Ridge near St. Stephen in the summer of 1910. An account of preventive work conducted in New Brunswick is appended.

**The grapevine scawler or writer (*Bromius vitis*)**, F. PICARD (*Prog. Agr. et Vit. [Ed. l'Est Centre], 32 (1911), No. 23, pp. 705-709, pl. 1*).—A brief account of a chrysomelid beetle (*B. vitis*) which attacks the grape, its habits and injury, and remedial measures therefor. This beetle is said to reproduce parthenogenetically.

**A new pest of cowpeas (*Agr. News [Barbados], 11 (1912), No. 267, p. 234*)**.—A lepidopterous insect which in October, 1911, caused a considerable amount of injury to cowpeas growing in a field near Bridgetown, Barbados, has been found by H. G. Dyar to represent a new genus and species, to which the name *Ballovia cistipennis* has been given. It is said that an insect causing similar injury to the horse bean (*Canavalia ensiformis*) occurs in St. Kitts, but up to the present time the adult has not been reared.

**Kumblihulas attacking crops in Mysore (*Amsacta albistriga*).** L. C. COLEMAN (*Dept. Agr. Mysore, Ent. Scr. Bul.* 3, 1912, pp. 12, pl. 1).—*A. albistriga* is said to be the most common of the hairy caterpillars attacking crops in Mysore.

***Æceticus platensis* ("Bicho de Cesto") and its destruction,** J. M. HUERGO (*Bol. Min. Agr. [Buenos Aires],* 13 (1911), No. 9, pp. 590-626, figs. 15; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases,* 3 (1912), No. 2, p. 586).—In the larval stage this lepidopteron attacks a large variety of fruit, forest, garden, and forage plants, stripping them of leaves and at times injuring the fruit. Among its important enemies are the ichneumonids *Pimpla brasiliensis* and *P. tomoyris*; the chalcids *Tetrastichus platensis* and *Smicra bergi*; and the tachinid *Phorocera xanthura*.

**Ways and habits of caterpillars,** H. W. B. MOORE (*Timchri, Brit. Guiana,* 3, ser., 2 (1912), No. 1, pp. 197-206).—Among the habits of caterpillars which the author mentions are those of cannibalism among caterpillars of *Laphygma frugiperda*, *Callidryas cubule*, and *Euptoieta heyesia*; the feeding of several species upon eggshells from which they have emerged; devouring their molted skins, etc.

**Bird enemies of the codling moth,** W. L. MCATEE (*U. S. Dept. Agr. Year-book* 1911, pp. 237-246, pls. 2).—In this paper the author reviews the evidence relating to the destruction of the codling moth by birds, both native and exotic, with references to the literature.

"Birds are recognized as the most effective natural enemies of the codling moth. In some localities they destroy from 66 to 85 per cent of the hibernating larvae, and their work in large measure accounts for the small spring broods of the insect. . . . Thirty-six species of birds are known to prey upon the codling moth in the United States. These species belong to 13 families, of which the most important, so far as number of species on the list is concerned, are the woodpeckers, titmice, and sparrows. Especially valuable species are the downy woodpecker, Bullock oriole, black-headed grosbeak, and bush tit. At least 10 species of foreign birds have been recorded as enemies of the codling moth, and there has been considerable agitation for the introduction of one or more of them. The importation of foreign species is, however, notoriously dangerous, and if successful would result in crowding out native species probably of greater value."

**Experiments on infection with flacherie through food, and the means of preventing its spread,** A. MOZZICONACCI (*Monit. Soies,* 1911, No. 255½; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases,* 2 (1911), No. 8-10, pp. 2253, 2254).—The results of the author's investigations show that flacherie is very easily and surely transmitted by the absorption of dust from nurseries where the disease has existed. Dust kept in a bottle 12 years does not lose its virulent action. Lysoform appears to exert a greater destructive power than sericine on the organisms of flacherie and grasserie.

**The mosquito plague of the Connecticut coast region and how to control it,** W. E. BRITTON (*Connecticut State Sta. Bul.* 173, pp. 3-14, pls. 4, figs. 2).—"The mosquito plague of southern Connecticut is composed chiefly of 2 species of salt marsh mosquitoes—the brown salt marsh mosquito (*Culex cantator*) and the banded salt marsh mosquito (*C. sollicitans*), which breed in the brackish stagnant pools of the salt marshes and fly inland several miles in search of their food. . . .

"The rain barrel mosquito (*C. pipiens*) breeds in rain water barrels, tin cans, and other receptacles along the shore, and certain other species of *Culex*, as well as the malarial mosquito, *Anopheles*, may breed in the fresh water pools next to the highland, yet these are all local, fly only short distances and form

only a small part of the mosquito plague of the coast region. The salt-marsh region of Connecticut contains 34.79 square miles, or 22,264 acres, more than half of which has in past years been drained for salt-hay farming. During recent years the marshes have received little attention, the ditches have become filled and probably breed more mosquitoes than they did 30 or 40 years ago. . . .

"The cost of draining the Connecticut marshes will vary, but may be done by contract at from \$5 to \$10 per acre, and should not average more than \$8. The entire salt-marsh area of Connecticut can be drained for less than \$200,000.

"The increase in yield of salt-marsh hay will soon pay the cost of draining and may do so in a single season."

**Notes on mosquito eradication.** G. W. MCCOY (*Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Rpts., 27 (1912), No. 26, pp. 1029-1034*).—The notes here presented are based upon the experience of a rather extensive antimosquito campaign undertaken in the city of Honolulu, Hawaii. The data relate to the distribution of different species of mosquitoes; antilarvæ agents and procedures employed; and methods of treating different breeding places.

**Fly larvæ and rabies virus.**—Lyssicide action and virus transmission, C. FERMI (*Centbl. Bakt. [etc.], I. Abt., Orig., 61 (1911), No. 1-2, pp. 93-97*).—In a first series of experiments the author fed fly larvæ on the brains of rabies cases and then tested their virulence by emulsifying and injecting subcutaneously. In a second series a fixed virus and fly larvæ were rubbed into an emulsion and likewise injected subcutaneously. The results obtained indicate that the rabies virus can not be transmitted through fly larvæ.

It appears that the fly larvæ emulsion has an attenuating effect upon a fixed virus, either through its direct action upon the virus or through its indirect action upon the organism. It possesses no absolute lyssicidal power, since a virus mixed with fly larvæ emulsion is found to be virulent when administered subdurally.

**Note on a venomous dipteron,** TERESA JOAN (*Bol. Min. Agr. [Buenos Aires], 14 (1912), No. 4, pp. 363-885, pl. 1, figs. 12*).—This paper describes *Melusina (Simulium) dincllii*.

**The grain flies, with particular consideration of their economic importance and the dependence of their appearance on meteorological conditions.** K. STRÖMER and R. KLEINE (*Fühling's Landw. Ztg., 60 (1911), No. 20, pp. 682-703, figs. 3*).—The species here considered are *Hylemyia coarctata*, *Limnophora* sp., *Chlorops tanipus*, *Oscinis frit*, *O. pusilla*, *Agromyza graminis*, and *Hydrellia griseola*.

**The influence of frost on the development of different varieties of barley in the presence of the frit fly,** N. LITVINOV (*Trudy Būuro Prikl. Bot. (Bul. Angew. Bot.), 4 (1911), No. 11, pp. 541-551*).—This paper deals with the effect of frost on barley and the relation of such to injury by *Oscinis frit*.

**The value of predaceous beetles in destroying insect pests,** A. F. BURGESS and C. W. COLLINS (*U. S. Dept. Agr. Yearbook 1911, pp. 453-466, pls. 6, figs. 6*).—This is a general discussion of the usefulness of predaceous beetles, including native lady beetles and native ground beetles, facts concerning the importation of several species of predaceous beetles, and a comparison of *Calosoma sycophanta*, an account of which has been previously noted (*E. S. R., 26, p. 350*) with native *Calosoma*.

**Preliminary report on the alfalfa weevil,** F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Bul. 112, pp. 47, pls. 13, figs. 27*).—This is a report of investigations commenced April 1, 1910, and covering the work up to November 15, 1911, conducted in cooperation with the Utah Station (*E. S. R., 24, p. 458; 25, p. 160*).

"Up to September, 1911, the insect had extended its area of diffusion directly northward as far as Tremonton, east to Evanston, Almy, and Lyman, Wyo.,

and northeast to Cokeville, Wyo., Randolph and Laketown, Utah, and Fish Haven, Idaho."

While previously reported to be *Phytonomus murinus*, a further study has shown the pest to be *P. posticus*, a closely related insect, which is much more common and injurious to alfalfa in Europe, western Asia, and northern Africa, where it is generally known as *P. variabilis*. A much larger species, *Hypera punctata*, the clover-leaf weevil, has recently been collected at Malad, Idaho, and Ogden, Utah.

It has been found that the females do not always confine themselves to alfalfa stems in ovipositing, eggs having been discovered in the stems of the ground plum (*Astragalus arcticus*) and larvae found feeding on *A. utahensis*. In 1910 oviposition was found to commence early in March and was at its height by the middle of May. Evidence was found of a partial second generation. In cage experiments it was found that in combination with alfalfa the larvae fed freely on sweet pea, Utah milk vetch, string bean, obtuse-leaved vetch, narrow-leaved vetch, white clover, red clover, alsike clover, yellow sweet clover, white sweet clover, *Medicago lupulina*, *M. cehinus*, *M. hispida nigra*, *M. hispida confinis*, *M. hispida cerebellum*, *M. muricata*, *M. orbicularis*, *M. scutellata*, black locust, and fenugreek. When no other food was offered the larvae fed upon *Hedysarum mackenzii*, *Astragalus orophylus*, downy lupine, chick pea, *Vicia atropurpurea*, *V. dispana*, spring vetch, hairy or winter vetch, and spider plant, but these were refused when offered alfalfa.

Field experiments in destroying the weevil by means of street sweepers, brushing with a wire brush machine, which crushes the larvae and pupae, cultivation in connection with irrigation, and by a burning machine are briefly reported. The results seem to indicate that as a protection for the second crop the use of the street sweeper is of considerable value. In experiments with the brush machine it proved very effective in crushing the larvae and pupae among the stubble. An examination showed that while the treated field was in good condition with few larvae, the nearby, untreated field was bare and brown from weevil attack. Good results were obtained from cultivation in connection with irrigation. Experiments were carried out with a machine constructed with the idea of burning over alfalfa fields after the removal of the first crop for the purpose of destroying the weevils in any state of development remaining in the field. "Oil was pumped from a barrel in the conveyance to which this machine was attached and forced through a rubber hose into a supply pipe which fed the nozzles and burners underneath. The oil under pressure came forth from the burners as a mist of fire blowing into the stubble and against the ground." A sheet-iron cover served to hold the heat down while an oven passed slowly over the surface. In its unperfected state the machine did effective work and offered ideas of value, warranting the construction of more efficient burners.

The predaceous enemies of the weevil include 3 species of lady beetles (*Coccinella 9-notata*, *Hippodamia spuria*, and *H. convergens*), the malachid beetle *Collops bipunctatus*, the tenebrionid beetle *Elcodes sulcipennis*, and the mite *Erythraeus arvensis*. The predaceous mite *Pediculoides ventricosus* introduced from Indiana in March, 1911, did not attack either the larvae or pupae and while it fed freely upon the eggs of the weevil, where they were easily accessible, it seemed unable to gain access into many of the egg masses through the ordinary egg punctures. Only one specimen of a single true parasite of the alfalfa weevil, namely, *Ænopegimorpha phytonomi*, has thus far been found in America. Two egg parasites, *Anaphcs* sp. and an undetermined pteromalid, the latter of which is very effective in controlling the alfalfa weevil in Italy, were introduced from that country. Five parasites of the larvae and pupae, namely, an undetermined pteromalid, which attacks the larvae and has actually

colonized itself in the field; *Canidiella curculionis*, which oviposits in the larvae of the alfalfa weevil in different stages of development; *Phygadeuon* sp.; an undetermined species, probably *Mesochorus nigripes*; and *Itoplectis masculator* were also introduced from Italy. An additional species (*Hemiteles* sp.) about which very little is known may prove to be either a primary or secondary parasite. A list is given of 31 species of birds found by E. R. Kalmbach to feed upon the alfalfa weevil in Utah during 1911. From observations made in the vicinity of Salt Lake City on June 13, it is estimated the one-fifth of the cocoons contained larvæ or pupæ killed by the fungus *Empusa sphaerosperma*.

**The rice water-weevil and methods for its control (*Lissorhoptrus simplex*),** E. S. TUCKER (*U. S. Dept. Agr., Bur. Ent. Circ. 152, pp. 20, figs. 2*).—This circular, based upon investigations conducted by C. E. Hood in 1910 and the author in 1911 in cooperation with the Louisiana Station, summarizes the available practical information concerning the weevil and measures for its control.

This insect is stated to be the most serious enemy of rice in the Southern States. In the larval stage it is known to rice growers as the "rice root-maggot." In this stage it commits severe injury to rice plants by destroying the roots; some harm is done by the adults in feeding on the leaves. General statements of the shortage of production caused by this pest vary from as low as 1 per cent at Beaumont, Tex., to 75 per cent in some fields at Stuttgart, Ark. In addition to cultivated rice its food plants include arrowhead, bulrush, galingale, water lily, spatter-dock, wild rice (*Zizania aquatica*), Walter's swale grass (*Paspalum membranaceum*), etc. The weevil swims readily on or beneath the surface and feeds, rests, and mates almost as frequently in the water as above it.

"The insect chooses food plants that grow in wet places and it breeds only where it finds water. Eggs are evidently laid on roots in water or mud, under which conditions the larvæ hatch, feed, grow, and transform into pupæ, and finally the adults mature and emerge. Two generations may possibly be produced in a season, but one generation seems to be the rule. Adults pass the winter in hibernation, appearing in spring and invading the rice fields.

"The most practical means of controlling the weevil consists in the practice of draining and allowing infested rice fields to dry sufficiently at the proper time or before the attacks of the larvæ have greatly weakened the plants. Alternate flooding and drying, if carried out properly, will accomplish the same results. Very shallow flooding or soaking of fields restrains infestation. Fertilization assists the plant to overcome injury. Considerable numbers of weevils can be captured at lights and destroyed, and the possibility of poisoning them in fields needs to be put to the test. Cultural management should be directed with the view of enforcing every advantage against the weevil that will be consistent with the welfare of the crop."

**Mexican cotton boll weevil,** W. D. HUNTER and W. D. PIERCE (*U. S. Senate, 62. Cong., 2. Sess., Doc. 305, 1912, pp. 188, pls. 22, figs. 34*).—This bulletin, prepared as Bulletin 114 of the Bureau of Entomology of this Department, and which is an elaboration of Bulletin 51 (*E. S. R., 17, p. 161*), gives a comprehensive account of the more important available information concerning the boll weevil. Since 1905 the work on the investigation of this important pest has been continued by the Bureau of Entomology and by various other agencies. As a result of this recent work, certain features of the life history of the pest have received full treatment in publications of the Bureau, previously noted, as is the case with hibernation (*E. S. R., 21, p. 761*), natural control (*E. S. R., 19, p. 756*), parasites (*E. S. R., 27, p. 59*), proliferation (*E. S. R., 18, p. 251*), and repression (*E. S. R., 20, p. 853*).

The cause of European foul brood, G. F. WHITE (*U. S. Dept. Agr., Bur. Ent. Circ. 157, pp. 15, figs. 10*).—In feeding experiments with *Bacillus alvei*, *Streptococcus apis*, *B. mesentericus vulgaris*, *B. orpheus*, and *Bacterium curydicæ*, the author was unable to induce the disease commonly known as European foul brood.

“Considerable quantities of filtrate from aqueous suspensions of crushed diseased larvæ were fed to healthy colonies and in no instance was European foul brood produced. This eliminated tentatively the probability of there being an ultra-microscopic virus in European foul brood capable of producing the disease. *Bacillus pluton* [= *Bacillus Y*] (*E. S. R., 20, p. 857*), therefore, was the only factor that was not so eliminated from the list of possible exciting causes of the disease and became thus the probable exciting cause of European foul brood. When this organism was studied in larvæ in which the disease could be suspected by inspection alone, one or more species of bacteria were sometimes found to be present also. These, when present, however, occurred in relatively small numbers.

“The disease was then studied in a still earlier stage; i. e., before its presence could be detected by gross examination of the larvæ. This was done by cultures in part, but principally by fixing and sectioning larvæ during the incubation period of the disease. This study demonstrated that in the production of the disease *B. pluton* was the first invader of the healthy larvæ.”

Papers on insects affecting stored products.—The broad-bean weevil (*Larid rufimana*), F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Bul. 96, pt. 5, pp. 59–82, figs. 10*).—This weevil, commonly known as the bean beetle or bean seed beetle in Europe, has frequently been brought to the United States and Canada in its food supply, but there was no positive proof of its having become established in North America until 1909. In Europe it is common and destructive and especially infests the broad, horse, or Windsor bean (*Vicia faba*) and, it is said, peas and some other legumes.

The species is known to occur in middle and southern Europe and northern Africa; has long been credited as being a pest in England; and is recorded from the Canary Islands. In 1893 the author found this species commonly in many exhibits of broad or Windsor beans at the World's Columbian Exposition. In September, 1909, living specimens were received from San Luis Obispo, Cal., in horse beans, which have been grown quite extensively in that region for feeding stock. It appears to have become established in several localities in the State and bids fair to become a most formidable drawback to the cultivation of broad beans. Records of the occurrence of this pest in imported beans are briefly discussed. Notes on Occurrence in California (pp. 64, 65) and Experiments with Remedies (pp. 74–80), by W. B. Parker, are incorporated in the paper. Parker states that the weevil was first observed and captured in broad beans in Sacramento on March 25, 1911.

“The female weevil begins to deposit her eggs on the young seed vessel in the blossom before and after the former has developed into a pod. Here the eggs hatch and the larvæ penetrate into the growing seeds, each gnawing a gallery for itself, which it lengthens from time to time, as needed. When full grown, the larva transforms to pupa within the accumulated frass and develops later into the beetle stage.” Like the closely related pea weevil (*L. pisorum*) it produces only a single generation a year and hibernates as an adult in the seeds.

Germination tests of infested beans from California show that “even in cases where a single individual weevil attacks a broad bean, less than 60 per cent of such infested beans germinate, whereas when 4 or 5 beetles find lodgment in a single seed, 32.3 per cent, or about one-third only, germinate. There is no

doubt that seeds containing holes made by this beetle are unfit for planting, as, even with perfect germination, the opportunity for the entrance of water into the seeds stimulates decay and the seed frequently rots before germination."

The natural enemies of this weevil include 3 hymenopterous parasites, *Sigalphus pallipes*, *S. thoracicus*, and *Chremylus rubiginosus*, first recorded by J. Curtis in England in 1863, and the predaceous mite *Pediculoides ventricosus*, which was observed in Sacramento in 1911. Experiments reported show that 140° F. is the lowest temperature at which all of the weevils are sure to be killed and that the germinative power of the bean is not seriously injured until the temperature reaches 160° or over. "Fumigation with bisulphid of carbon, at the rate of about 2 or 3 lbs. of the chemical to each 1,000 cu. ft. of air space for 48 hours, is a perfect remedy in an air-tight receptacle, as in the case of other bean and pea weevils." Directions are given for the construction of a fumigator.

An annotated bibliography of 29 titles is appended.

**Keeping native bees in Paraguay**, A. DE WINKELRIED BERTONI (*Rev. Agron. y Bol. Estac. Agron. Puerto Bertoni*, 4 (1910), No. 8, pp. 21-24; abs. in *Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intcl. and Plant Diseases*, 2 (1911), No. 8-10, pp. 2258, 2259).—The author, who has made several attempts to domesticate the native bees of Paraguay, obtained several successful results. The species reared belong to the genera *Melipona*, *Lestrimellita*, and *Trigona*. These bees are said to yield a more aromatic honey and higher priced wax than does the common honeybee. The bees of the genus *Melipona* are docile to domestication but are attacked by a dipterous parasite.

**The behavior of *Prospaltella berlesii* in Italy**, A. BERLESE (*Redia*, 7 (1911), No. 2, pp. 436-461; abs. in *Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intcl. and Plant Diseases*, 3 (1912), No. 3, p. 831).—The author, who introduced and has been conducting investigations relative to the value of *P. berlesii* in combating *Aulacaspis (Diaspis) pentagona*, finds that it adapts itself perfectly to the climate of upper Italy and is not injured by even the most intense winter cold. This parasite reproduces very readily in the regions where the winter is less lengthy and milder, as in Genoa and environs of the Garda Lake, and more slowly in the regions with severe winter as in Piedmont, where it probably goes through one or two generations less than in the hotter parts.

**Parasitic enemies of the Mediterranean flour moth (*Ephestia kuehniella*)**, W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 4, pp. 307-311, figs. 2).—A new parasite, described by Cameron as *Amorphota cphestia*, has been found to parasitize the Mediterranean flour moth in Victoria and New South Wales. "The parasites confine their attention to the many flour moth caterpillars that crawl out and pupate in the dust, flour, and rubbish on the walls and open places. They can not, or will not, enter the closed places, so that while the parasites have a considerable value in any mill infected with the Mediterranean flour moth when they destroy all the outside caterpillars, they also have their limitations, as they never make their way into the places where the main body of the caterpillars are feeding and pupating." Four specimens of *Bracon (Hadrobracon) heक्टर* were bred from waste flour received from flour mills.

**A hymenopterous parasite of *Ixodes***, R. DU BUYSSON (*Arch. Par.*, 15 (1912), No. 2, pp. 246, 247, fig. 1).—*Loxodiphagus caucurtei*, reared from many *Ixodes* nymphs collected on deer at Chantilly, Department of Oise, France, in October and at Fontainebleau in November is described as new to science. The species is closely related to *I. tcranus*.

**The zoocecidis of North Africa**, C. HOUARD (*Ann. Soc. Ent. France*, 81 (1912), No. 1, pp. 128, figs. 268).—In this paper 230 ceecids are dealt with.

**The fowl tick (*Argas persicus*)**, W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 3, pp. 254-261, figs. 4).—This paper contains new information which has come to hand regarding the identity and range of the fowl tick.

**Trombididæ**, A. BERLESE (*Redia*, 8 (1912), No. 1, pp. 1-291, pl. 1, figs. 137).—This is a synopsis of the family.

**The leaf blister mite (*Eriophyes pyri*)**, A. L. QUAINANCE (*U. S. Dept. Agr., Bur. Ent. Circ.* 154, pp. 6, figs. 4).—This is a brief summarized account of the knowledge of the blister mite, a report of studies of which by P. J. Parrott, H. E. Hodgkiss, and W. J. Schoene has been previously noted (*E. S. R.*, 18, p. 955).

**On the parasitism of a cynipid (*Aulax scabiosæ*) by *Pediculoïdes ventricosus***, G. R. BLANC (*Bul. Soc. Zool. France*, 37 (1912), No. 5, pp. 191-197, figs. 5).—The author reports a case of accidental parasitism of a gallicolous cynipid (*A. scabiosa*) by the acarid *P. ventricosus*. A bibliography of 18 titles is appended.

**Physiological investigations of entomophytous fungi**, P. PORTIER (*Recherches Physiologiques sur les Champignons Entomophytes*, Paris, 1911, pp. 47, figs. 10; *abs. in Zentbl. Allg. u. Expt. Biol.*, 2 (1912), No. 21-23, pp. 565, 566).—This work deals largely with studies made of a fungus (*Isaria*) and a diplococcus, which live symbiotically in the interior of the caterpillar, chrysalis, and adult of the lepidopteron *Nonagria typha*, which mines in the pith of *Typha latifolia*.

**Cold storage of furs and fabrics**, E. F. TWEEDY (*Sci. Amer. Sup.*, 74 (1912), No. 1905, pp. 10, 11).—This article describes the manner of applying cold in preventing injury by clothes moths. While a temperature of 40° F. is effective, the temperature most commonly carried in cold storage rooms ranges from 20 to 26°. At these lower temperatures the furs retain a fresh and glossy appearance, and the flexibility of the skins is preserved by a lessening of the evaporation of their natural oils.

## FOODS—HUMAN NUTRITION.

**The net weight or volume of food products which are sold in packages**, J. P. STREET (*Connecticut State Sta. Bul.* 172, pp. 35).—The text of the Connecticut law of 1911 on this subject is given, the general question of weight and volume of goods sold in packages is discussed, and data are reported regarding the size and weight of standard cans and results of the determination of the gross and net weights of a large number of samples of canned and package goods.

On the basis of weighings of 623 samples of canned vegetables, the author states that "the uniformity in weight of the contents of individual cans of the same brand of vegetables, excepting artichokes, peppers, succotash, and tomatoes, is very striking, and it appears that, in general, the manufacturer at present packs a fairly uniform amount of the vegetable in cans of the same size."

Observations regarding the amount of liquid and solid material in canned fruits and vegetables are reported but deductions are not drawn as it is expected to continue the work.

With 164 samples of canned fruits, the uniformity of weight was not so great as with vegetables, and in the author's opinion a somewhat greater allowance should be made, owing to the larger size of the fruits.

The 120 samples of canned fish, meats, and soups showed considerable uniformity in weight, with the exception of fish flakes, which showed much irregu-

larity in packing, and herring, which naturally varied because of the size of the fish.

Weighings of 257 packages of preserves, jelly, sirups, molasses, honey, pickles, ketchups, and condensed milk, showed that "all of the tin cans and most of the glass bottles of the same size showed fairly uniform weights."

In the case of biscuits and crackers, all but 4 of the 235 packages, representing 8 manufacturers and 27 brands, were guaranteed both as to the number of biscuits and the weight of the packages. "The deviations from guaranteed weight were exceedingly small."

Some weighings were made of packages of macaroni and similar pastes, prepared flour, baking powder, miscellaneous foods, and dried fruits. Of the latter, apples, currants and raisins showed only small variations while dates and prunes showed somewhat larger.

Of 594 samples in which the weight was stated, weighings showed that 517 of the samples either exceeded the claimed weight or were deficient by less than 0.25 oz. Seventy-seven of the samples showed a tendency toward short weight, but in 20 cases the deficiencies seemed to be exceptional. "The . . . [figures] show that manufacturers have little difficulty in satisfying the weights they claim for their products, and the . . . [data in the report] show that nearly all the products examined are packed with reasonably uniform weight." Additional weighings with other samples gave similar results.

Studies were also made of the shrinkage of dried fruits kept for different lengths of time, the results, according to the author, showing that "dried fruits naturally shrink from 4 to 28 per cent, depending upon the kind of fruit. It is not reasonable to expect that a manufacturer can so label his package as to net weight, as to cover all natural conditions liable to occur between the time it is packed and when the consumer buys it. On the other hand, the packer can control the weight of the fruit at time of packing. It seems reasonable and just, therefore, to require the packer to state on the label the net weight of the fruit when packed."

In general throughout the bulletin, recommendations are made relative to the allowances which should be permitted for variations in weight in the examination of goods sold in package form.

**Food inspection decision** (*U. S. Dept. Agr., Food Insp. Decision 145, p. 1*).—This decision has to do with oats and barley bleached with sulphur.

**Decomposition and its microscopical detection in some food products**, B. J. HOWARD (*U. S. Dept. Agr. Yearbook 1911, pp. 297-308, pls. 5*).—Causes of decay, methods of examination, molds, yeasts, bacteria, and animal invasions in food-stuffs are discussed with special reference to their detection by means of the microscope, as well as the susceptibility of different products to decay, organisms that may be properly present, and economic considerations. The article is based on the author's studies and is illustrated with reproductions of microphotographs. Marketing by the consumer of crops in proper condition, the effect of this upon losses from decay to the canner, and similar questions are also discussed.

"To efficiently solve the problem, the method of handling some products must be changed, since under present conditions it is practically impossible in some cases to get them to market in proper condition. In such an event it may be necessary to pack the product nearer the source of supply, instead of depending upon raw material that has spent a sufficiently long time in preparation to allow a more or less advanced state of decomposition to occur. The question of handling, from producer to consumer, is therefore of primary importance, as well as the methods of manufacture; in fact, the two problems are so closely related that no solution is practicable that does not consider both factors."

**Green vegetables and their uses in the diet.** C. F. LANGWORTHY (*U. S. Dept. Agr. Yearbook, 1911, pp. 439-452, fig. 1*).—The classification of green and succulent vegetables, their color, flavor, and food values, their quality and factors which influence it, the preparation of green vegetables for the table, and canning and preserving vegetables are the principal questions considered in this summary of data on the nutritive value of this group of foodstuffs.

While green and succulent vegetables do not add greatly to the total nutrients and fuel value of the diet, they do increase the wholesomeness in three ways, namely, by supplying mineral constituents less abundant in some other common food materials, by providing bulk for the normal digestion of the more concentrated food materials, and by making the diet more varied and attractive, the last being perhaps the most important consideration for persons living under usual conditions on an ordinary mixed diet. Furthermore, green vegetables require relatively little preparation, many needing only to be washed before serving, while those which are eaten cooked are usually better when simply prepared.

**Tropical fruit recipes and confections.** EFFIE S. ROLFS (*Proc. Fla. State Hort. Soc., 24, (1911), pp. 119-138*).—A collection of recipes for the preparation and use of tropical fruits, particularly those grown in Florida, is given.

**Foods—nutrition and digestion.** SUSANNA COCROFT (*Chicago, 1912, 2. ed., pp. 315*).—The properties and nutritive value of foods, theories of nutrition, diets suited to abnormal conditions, and other topics are discussed. An appendix contains recipes.

**Concerning experimental scurvy: A contribution to the influence of a one-sided diet.** A. HOLST and T. FRÖLICH (*Ztschr. Hyg. u. Infektionskrank., 72 (1912), No. 1, pp. 1-120, pls. 3*).—The authors found that when guinea pigs were fed different grains or bread exclusively, a disease was produced in about a month which had the same characteristics as scurvy. Like scurvy, it was prevented or cured by feeding cabbage, carrots, or dandelions. The protective power of fresh vegetables was generally lost or weakened by cooking; for instance, cabbage cooked at from 110° to 120° C. had less protective power than cabbage cooked at 100°. The fresh vegetables also lost their prophylactic power if dried for a long time, as was also the case with antiscorbutic vegetables used as human food. The juice of cabbage leaves, as distinguished from the leaves themselves, lost some of its antiscorbutic power if heated for 10 minutes at from 60 to 70 or 100°.

From their studies, the authors conclude that the antiscorbutic properties are due to compounds not yet identified, which are weakened or destroyed by heat. In general, they believe that acidosis is not the cause of scurvy.

The extract obtained by treating freshly dried cabbage with a 0.5 per cent aqueous solution of citric acid possessed strong antiscorbutic properties. Extracts obtained with absolute alcohol or petroleum ether did not possess such properties.

**A contribution to the etiology of experimental scurvy in guinea pigs.** V. FÜRST (*Ztschr. Hyg. u. Infektionskrank., 72 (1912), No. 1, pp. 121-154, figs. 5*).—Dried beans, lentils, and almonds were used in the experiments reported, as well as mixed rations. The author found that other dried seeds fed alone produced scurvy in the same way as dried grains, though the disease occurred later and in milder form.

The effects of a mixed diet, chiefly of preserved and dried food, varied with the character of the diet and the proportion of antiscorbutic material it contained. Allowing the seeds to sprout in certain cases rendered them antiscorbutic. According to the author, the antiscorbutic properties of certain foods are not attributable to protein, fat, carbohydrates, cellulose, or salts, or to any

chemical constituent which he was able to identify. In the same way he does not think the disease attributable to enzymes in general, to any special enzymes, or to any infection.

The general conclusion is that death results from under-feeding but that this in itself is not the cause of the disease.

**Experimental studies of infantile scurvy.** T. FRÖLICH (*Ztschr. Hyg. u. Infektionskrank.*, 72 (1912), No. 1, pp. 155-182).—The author studied especially the effects of cooking milk, and found that in general the exclusive use of either raw milk, boiled milk, or milk heated to a high temperature eventually produced a disease having the characteristics of scurvy, and that the use of lime juice had a beneficial effect which was not the case with cabbage or sodium citrate.

The author also studied the effects of raw milk added to a ration of oats. He notes that raw milk hindered the occurrence of scurvy, while milk heated for 10 minutes at 100° C. had lost this property. In an attempt to determine the different temperatures at which milk loses this protective power, he found that milk heated 30 minutes at 70° prevented scurvy.

**The introduction of maize into Italy and pellagra.** C. L. ALSBERG (*Reprint from South. Med. Jour.*, 1912, Apr., pp. 170-172).—This article calls attention to certain statements made in the literature that have caused confusion in the terms applied to maize. The discussion has especial reference to the occurrence of pellagra in Italy.

**The chemical nature of the substance which cures polyneuritis in birds induced by a diet of polished rice.** C. FUNK (*Jour. Physiol.*, 43 (1911), No. 5, pp. 395-400; *abs. in Jour. Chem. Soc. [London]*, 192 (1912), No. 592, II, p. 186).—The occurrence of polyneuritis in birds fed a diet of polished rice is due to the lack of a substance which is present in the polish in minute quantities, probably not more than 0.1 gm. per kilogram of rice. This substance, according to the author, is an organic base which is completely precipitated by phosphotungstic acid, silver nitrate, and barium hydroxid. It yields a crystalline nitrate. The curative dose for pigeons is very small.

Other analytical and chemical data are reported.

**A new respiration calorimeter for use in the study of problems of vegetable physiology.** C. F. LANGWORTHY and R. D. MILNER (*U. S. Dept. Agr. Yearbook 1911*, pp. 491-504, pls. 3).—Preliminary experiments having shown that ripening fruit (bananas) could be studied with the respiration calorimeter and that measurable quantities of carbon dioxide and water vapor were given off, oxygen absorbed, and heat liberated, and that the determination of such factors was important in considering problems which are being studied by the Department, a small respiration calorimeter was built of special size and construction, and particularly suited to the study of ripening fruit and other problems of plant life.

In principle and plan, it corresponds to the large respiration calorimeter which is used for experiments with man (E. S. R., 27, p. 466), although improvements in grouping accessory apparatus have been introduced and some new regulating devices have been installed. These greatly lessen the labor of conducting the experiments and which insure even greater accuracy, and make the apparatus as regards heat measurements practically self-regulating and self-recording. The new respiration calorimeter is especially designed for the study of ripening fruit and other vegetable products. "However, it is so constructed that the respiration chamber can be removed and another substituted for it, of the same size but with different interior arrangements, or of smaller size, should this be desirable. This would not involve any change in

the recording and controlling devices and other accessory apparatus. In other words, it would be possible, with little additional labor, to adapt the apparatus to the study of additional problems, such, for instance, as the incubation of eggs and the changes which take place in curing and storing meat products and cheese, or by making suitable provision for the collection of excretory products and for the comfort of the subjects, it would be possible to adapt the calorimeter to experiments with laboratory animals, should the work of the Department make this necessary."

### ANIMAL PRODUCTION.

**Native cacti as emergency forage plants.** J. J. THORNER (*Arizona Sta. Bul.* 67, pp. 457-508, pls. 8).—This gives a report of a number of years' experience in planting both spiny and spineless cacti for stock feeding.

Both the prickly pears and chollas are recommended as emergency forage, the former because they grow more readily from cuttings, suffer less from the effects of singeing and close browsing than chollas, and are best adapted for planting on the range with the idea of feeding the green vegetative parts after singeing or chopping them. Chollas are useful for their crops of fruit, the best yields being obtained from moderately large plants with a maximum vegetative growth, and should not be singed or otherwise cut back except in extremity.

Spineless cacti of the Monterey or Chico varieties even in a rabbit-proof fence failed to make successful growth except when irrigated, being injured both by severe winter freezes and extreme heat and drought.

A key and short descriptions of the more common species of economic cacti and their habitat are given. There are also reports of tests with native cacti, and directions for growing and using cacti for cattle food.

**Nutritive value of cholla fruit,** A. E. VINSON (*Arizona Sta. Bul.* 67, pp. 509-519).—Metabolism experiments with cholla fruit, water grass, and the second cutting of alfalfa hay were undertaken with 2-year-old native Merino sheep. The water-grass hay consisted mainly of *Chloris elegans*. Water grass was given ad libitum with a small amount of alfalfa, until the animals became reconciled to the experiment. On the sixth day a small amount of cholla fruit was added to the ration, and the quantity gradually increased. It seemed to act as an appetizer, and the animals ate the hay with more relish, due probably to the acidity of the fruit, which is as sour as green grapes and also mucilaginous. After the tenth day cholla fruit was given ad libitum, together with 230 gm. of water grass and 250 gm. of alfalfa to 1 sheep, and an additional 50 gm. of alfalfa to the second sheep. On the thirteenth day the first sheep left a small residue of hay as well as of cactus, due in part to increasing atmospheric temperature. From this time on the water grass was withdrawn entirely and the alfalfa ration much reduced, although the cactus was supplied ad libitum. The experiment with the first sheep was discontinued on the nineteenth day on account of the heat. With sheep No. 2 the experiment was discontinued on the twelfth day for the same reason.

There was a heavy loss in the nitrogen balance for the first 2 days, due to the change in ration from alfalfa to one composed largely of water grass, and also due in part to the restraint and unrest caused by the harness and other apparatus. From the eighth to the fourteenth day, with increased cactus ration and a restricted supply of alfalfa, the nitrogen income was in excess of the nitrogen outgo. During this period, except on the ninth day, 4.85 lbs. of cholla fruit was placed before the animals daily, so that on those days the animals would probably have eaten more had it been accessible.

After the fourteenth day the feces became physically abnormal, and it was evident that the animal could not maintain its nitrogen equilibrium with cholla fruit alone, but regained both strength and flesh when again given alfalfa.

Attempts were made to repeat the experiment, using pads of prickly pear (*Opuntia discata*), which were singed and cut into small squares, but the sheep refused to touch them. This experience is in accord with the observations of shepherds, which show that sheep eat greedily the fruits of cactus but never take the stems. In the case of cattle the joints, as well as the fruit, can be utilized.

The coefficients of digestibility of the water-grass hay used in the ration were as follows: Dry matter 47.36, protein 50.08, ether extract 27.39, carbohydrates 45.81, crude fiber 57.51, and ash 32.87 per cent. The coefficients of the cholla fruit were dry matter 60.75, protein 49.8, ether extract 74.15, carbohydrates 76.09, crude fiber 12.79, and ash 40.12 per cent. The analysis of water-grass hay was as follows: Dry matter 94.2, protein 7.56, ether extract 1.09, carbohydrates 36.41, crude fiber 31.18, and ash 17.96 per cent. The analysis of cholla fruit showed dry matter 21.11, protein 1.15, ether extract 0.87, carbohydrates 13.2, crude fiber 2.91, and ash 2.98 per cent.

"As a ration for maintaining sheep in a fair state of nutrition, cholla fruit alone would be required in amounts far in excess of the animals' capacity. At least 45 lbs. daily of the fresh fruit would have to be consumed. This would produce 10 lbs. or more of feces of normal consistency if scouring did not occur. The mineral constituents that would be absorbed from the intestine and require elimination by the kidneys would be excessive. Cholla fruit alone seems inadequate as a ration for maintaining the nitrogen equilibrium and, consequently, life, over any considerable period. However, with the aid of  $\frac{1}{2}$  to  $\frac{3}{4}$  lb. alfalfa hay, 6 or more pounds of cholla fruit daily would probably not only preserve life in a sheep of 120 lbs. shorn live weight for an indefinite time, but allow some gain. Similar results with quantities increased in proportion to live weight may be anticipated for range cattle. This would require 4 to 6 lbs. of alfalfa, or its equivalent in concentrates, and 50 or more pounds of cholla fruit per head per day."

**Feeding experiments with eosin barley,** GERLACH (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 4 (1912), No. 4, pp. 374-387).—Barley, when stained with eosin as required by law, when fed to swine did not affect unfavorably either the live animals or the quality of the meat. The iodine number and the melting point of the fat remained unchanged.

**Analyses of feeding stuffs,** H. B. McDONNELL ET AL. (*Id. Agr. Col. Quart.*, 1912, No. 56, pp. 4-7).—Analyses are reported of linseed cake, cotton-seed meal, meat meal, beef scrap, dried beet pulp, dried brewers' grains, gluten meal, malt sprouts, molasses feed, and mixed feeds.

**Commercial feeding stuffs of Pennsylvania in 1911,** J. W. KELLOGG (*Penn. Dept. Agr. Bul.* 223, 1912, pp. 171).—Analyses are reported of cotton-seed meal, linseed meal, corn-oil meal, distillers' grains, brewers' grains, malt sprouts, gluten feed, hominy feed, corn bran, corn flour, wheat offals, low-grade flour, rye offals, buckwheat offals, alfalfa meal, beet pulp, maize by-products, molasses feed, beef scrap, and proprietary mixed feeds.

**Analyses of feeding stuffs** (*Jahresber. Landw. Vers. Stat. Harleshausen*, 1911-12, pp. 15-23).—Analyses are reported of cotton-seed meal, peanut cake, sesame cake, rape cake, linseed cake, palm cake, coconut cake, soy-bean meal, susza cake, ajowan bran, wheat bran, rye bran, ground barley, barley bran, ground oats, rice meal, dried distillers' grains, brewers' grains, malt germ, molasses feed, sugar-beet chips, maize, oats, sugar beets, potatoes, beet leaves, meat meal, fish meal, feed lime, and mixed feed.

What the census tells about live stock, B. H. HIBBARD (*Country Gent.*, 77 (1912), No. 33, pp. 4, 5).—A discussion of the live-stock statistics of the 1910 census.

[Live stock in Tunis], A. J. PERKINS (*Jour. Dept. Agr. So. Aust.*, 15 (1912), No. 10, pp. 1000-1011, figs. 3).—This contains descriptions of the fat-tailed sheep, goats, cattle, camels, asses, mules, horses, and pigs in Tunis.

The finest cattle, A. KRAEMER (*Das Schönste Rind. Berlin, 1912, 3. ed., rev. and cul., pp. 310, pls. 4, figs. 82; abs. in Molk. Ztg. [Hildesheim], 26 (1912), No. 60, p. 1127*).—This is an enlarged and revised edition of a standard German work on judging cattle.

The meat industry, L. M. DOUGLAS (*London: Roy. Soc. Arts, 1912, pp. 34, figs. 23*).—This consists of the Cantor lectures before the Royal Society of Arts, February, 1912. It contains statistical data on the cattle, sheep, and swine industry and describes methods of packing and curing meat.

A history of the frozen meat trade, J. T. CRITCHELL and J. RAYMOND (*London, 1912, pp. XVIII+442, pls. 58*).—This contains a large amount of historical and statistical data on the export of beef and mutton from Australia, New Zealand, Argentina, United States, and Great Britain.

Investigations on the Bergschecken breed of cattle, and its position in the zootechnical system, E. KASERER (*Mitt. Ludw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien, 1 (1912), No. 2, pp. 163-215, pls. 2*).—This contains an account of the origin, characteristics, and past and present distribution of the type of cattle known as the Bergschecken and Ennstaler, and by other names. It is a native of Bavaria, Upper Austria, Salzburg, and Steiermark. Measurements made of the bones and of live animals are given.

Resorption in the stomach of ruminants, AGGAZZOTTI (*Clin. Vet. [Milan], Sez. Sci., 33 (1910), No. 1-3, pp. 54-75, pl. 1; abs. in Deut. Tierärztl. Wchnschr., 18 (1910), No. 30, pp. 446, 447; Jahrb. Wiss. u. Prakt. Tierzucht, 6 (1911), p. 177*).—The abomasum and reticulum were found to have only a small capacity for the resorption of water. A decrease in sugar was thought to be due to the decomposition by ferments and organisms carried into the stomach by means of the hay. The psalterium had a large resorption capacity for both water and sugar solution.

Fundus glands of pig's stomach, G. ULKAN (*Anat. Anz., 41 (1912), No. 2-3, pp. 78-80; abs. in Jour. Roy. Micros. Soc., 1912, No. 4, p. 394*).—The author finds that the epithelium of the pig's stomach is from the first a single layer, and sharply separated from the mesodermic tunica propria by a distinct membrana propria. The fundus glands arise in the epithelium without help from mesodermic elements. The primitive pits give rise to the definitive pits and fundus glands.

Forage crops for swine, L. A. WEAVER (*Missouri Sta. Circ. 55, pp. 163-166, figs. 3*).—A popular account, summarizing the results of work previously noted (*E. S. R.*, 25, p. 274), together with some additional data.

Hominy feed for fattening hogs, J. H. SKINNER and F. G. KING (*Indiana Sta. Bul. 158, pp. 267-279*).—The average of 3 tests in comparing hominy feed with corn meal for swine feeding gave the following results: On a ration of hominy feed and shorts 2:1, the average gain per head and day was 0.759 lb., at a cost of 6.31 cts. per pound. On a ration of corn meal and shorts 2:1, the corresponding gain was 0.636 lb., at a cost of 6.05 cts. per pound. In 4 trials, on a ration of hominy feed and tankage 20:1 the daily gain per head was 1.446 lbs., at a cost of 4.81 cts. per pound, and on corn meal and tankage 20:1, 1.203 lbs., at a cost of 4.31 cts. per pound.

"Hominy feed produces more rapid gains on hogs than does corn meal. Hominy feed produces gains on less grain than does corn meal. As a general rule, the high cost of hominy feed hinders its more general use as a hog feed and prevents its economical substitution for corn, except when the latter is very high in price."

Swine breeding in Madagascar and its future, J. F. BRIGANDAT (*L'Élevage du Porc à Madagascar son Avenir. Tananarivo, Madagascar, 1912, pp. 21*).—A general account of swine breeding and of recent progress made in the swine industry in Madagascar.

Forage rations for growing horses, W. P. SNYDER (*Nebraska Sta. Bul. 130, pp. 3-15, figs. 2*).—These tests were undertaken to determine the value of alfalfa pasture and alfalfa hay in maintaining colts from weaning time to maturity. Most of the dams of the colts were Montana mares, sired by a pure-bred Percheron stallion. There were 7 mule colts, and 32 colts in all.

All of the animals ran together in an alfalfa field containing alfalfa stacks from the time they were weaned about October 1, 1907, until January 1, 1908, when they were divided into 3 lots. During the weaning time and the remainder of the first winter they were fed 4 lbs. of grain per head per day consisting of corn and oats 2:1. None of the colts received grain regularly after the first winter, except the lot on prairie hay and cane hay, which was given emmer. During the summer that they were 2 years old they were broken into work, grain being fed during that time.

The average gains per head and day for 3 years were as follows: Alfalfa hay in winter and alfalfa pasture 0.61 lb.; alfalfa hay in winter and prairie pasture in summer 0.55 lb.; and prairie hay and cane hay in winter and prairie pasture in summer 0.48 lb. The average cost of feed per colt for the 3 lots was \$65.30, \$52.48, and \$45.48, respectively. The colts made a greater gain during the first winter and during the first summer after weaning than at any later period. The gains were also greater the second year than in the third year.

It was not considered profitable to pasture the alfalfa during the summer, or at least after the first summer, although it might have been profitable if the colts had been sold as yearlings or as 2-year-olds, if there had been some special incentive for getting rapid gains, or the cost of alfalfa pasture and the native grass pasture had been about the same. The alfalfa pasture put the colts in excellent condition.

Investigations on the chemical composition of the metacarpus of light and heavy horses, B. HART (*Untersuchungen über die chemische Zusammensetzung des Röhrebeins (Metacarpus) von Lauf- und Schrittpferden. Inaug. Diss., Univ. Jena, 1910, pp. 59; rev. in Jahrb. Wiss. u. Prakt. Tierzucht, 6 (1911), pp. 168-170*).—On the whole, the bones of the heavy horses contained more organic matter and less mineral matter than the bones of the light horses. Some minor differences in chemical composition were found, but it was concluded that there are greater differences in the form and physical properties than in the chemical composition of the bones of the 2 types. The influence of sex, age, and other factors are also discussed.

Origin and history of all breeds of poultry (*Chicago, Ill. [1912], pp. 64, pls. 8*).—This contains a brief account of the origin and history of all common varieties of chickens, ducks, and geese.

The handling and marketing of eggs, H. M. LAMON (*U. S. Dept. Agr. Yearbook 1911, pp. 467-478, pls. 2*).—A discussion of the causes of large losses due to faulty methods of marketing eggs, which is based largely on work previously noted (*E. S. R., 26, p. 78*).

Egg classification at New York (*N. Y. Produce Rev. and Amer. Cream., 34 (1912), No. 4, pp. 174, 176, 177, figs. 2; Farm Poultry, 23 (1912), No. 8, p.*

205).—This contains the rules which have been adopted by the egg committee of the New York Mercantile Exchange.

Double eggs, C. W. HARGITT (*Amer. Nat.*, 46 (1912), No. 549, pp. 556-560, figs. 3).—Two types of malformed eggs are illustrated and described.

Investigations on crooked-breasted fowls, C. D. STEWART (*Ann. Sci. Bul. Roy. Agr. Col. Cirencester, 1911, No. 3, pp. 73, 74*).—When both cock and hens had this defect it was found not to be inherited in the offspring. As it was produced by allowing chicks to rest on perches when young, it is thought that unsuitable perches or perching at too young an age may be the cause of the trouble.

Preliminary note on crosses between pheasants and fowls, J. R. AINSWORTH-DAVIS (*Ann. Sci. Bul. Roy. Agr. Col. Cirencester, 1911, No. 3, pp. 71, 72, pl. 1*).—A brief note on experiments in crossing a Mongolian pheasant cock with golden-pencilled Hamburg hens, and an old English game bantam cock with common hen pheasants.

Sex-linked inheritance in poultry, T. H. MORGAN and H. D. GOODALE (*Ann. N. Y. Acad. Sci.*, 22 (1912), pp. 113-133, pls. 3, figs. 4).—Crosses were made between Plymouth Rocks and Langshans\* and the American Dominique and Langshans. Data are reported on barring, shank color, booting, down color, white-feathered wings, and the color of bill and legs.

A case of sex-linked inheritance in the domestic pigeon, L. J. COLE (*Science, n. ser.*, 36 (1912), No. 919, pp. 190-193).—This contains additional notes to a brief report of work previously noted (*E. S. R.*, 21, p. 274).

Dun, yellow, and silver are considered as dilute conditions of black, red, and blue respectively, and the phenomenon of dilutions in this case furnishes another instance of sex-linked inheritance. A full report of the work is promised in the near future.

On the inheritance of tricolor coat in guinea pigs and its relation to Galton's law of ancestral heredity, W. E. CASTLE (*Amer. Nat.*, 46 (1912), No. 547, pp. 437-440).—The advantages of the Mendelian over the Galtonian interpretation of tricolor inheritance in guinea pigs and in Bassett hounds are pointed out.

Physiological sex determination, B. C. GRUENBERG (*Science, n. ser.*, 35 (1912), No. 902, pp. 593, 594).—A criticism of the argument by Robinson previously noted (*E. S. R.*, 26, p. 773) that the suprarenal capsules are concerned in the determination of sex.

"A more general criticism of Robinson's argument lies in the tacit assumption that sex differentiation means one thing in the higher vertebrates and man, and quite a different thing in the rest of the animal kingdom and in plants. It may well be that there are several distinct factors concerned in sex determination, but these must all belong to related categories. It is extremely improbable that sex is determined by an accessory chromosome among insects, by adrenalin among mammals, by traumatism among graminæ, say, and by ultra-violet rays among mosses."

The present position of the sex problem, R. HERTWIG (*Biol. Centbl.*, 32 (1912), Nos. 1, pp. 1-45, figs. 7; 3, pp. 129-146).—A compendious summary of investigations on the sex ratio, with special reference to Mendel's law and the accessory chromosome. A bibliography is appended.

Cell structure, H. STAUFFACHER (*Ztschr. Wiss. Zool.*, 95 (1910), No. 1, pp. 1-120, pls. 2, figs. 3; 98 (1911), No. 3, pp. 478-527, pl. 1, figs. 5; *abs. in Jour. Roy. Micros. Soc.*, 1912, No. 4, p. 393).—Among numerous other studies on the structure of cells in the lower animals, the author finds more or less nuclein in the nucleus of young ova but none in the nucleus of ripe ova. The head of the spermatozoon in *Anodonta* was found to be full of nuclein, and it is suggested

that this acts as a ferment in starting the process of growth in the ripe ova. There was an abundance of nuclein found in the sporocysts of Trematodes, which reproduce parthenogenetically.

These studies indicate that the presence of nuclein is closely associated with metabolism during rapid growth.

### DAIRY FARMING—DAIRYING.

**Dairying in connection with farming**, A. A. TURNER (*Alabama Tuskegee Sta. Bul.* 22, pp. 3-11).—A popular discussion on the advantages of dairying as a side issue in connection with general farming, including forms for dairy records.

**More winter dairying in South Dakota**, C. LARSEN (*South Dakota Sta. Bul.* 134, pp. 286-305, figs. 5).—This bulletin was written to show the advantages of having cows freshened in the autumn in order to increase the output of butter during the winter months. The topics discussed are shelter, silage, and other important conditions for successful winter dairying.

**Relation of dairy cow to producer and consumer**, O. F. HUNZIKER (*Hoard's Dairyman*, 43 (1912), No. 23, pp. 811-813, figs. 2).—This is an address presented at the meeting of the Indiana shippers of dairy products, 1912, and contains statistical data on the amount and value of dairy products, prices paid for milk fat, international trade in butter and cheese, and the value of the fertility contained in dairy products and shipped away from the farm.

**Relation between yields of milk and yields of fat in dairy cattle**, F. R. MARSHALL (*Amer. Breeders Mag.*, 3 (1912), No. 2, pp. 148, 149).—According to figures furnished by O. W. Reagin, the correlation between the pounds of milk and percentage of fat in Guernsey, Jersey, and Holstein cows was found in all cases to be a negative one, showing that high milk yields are at the expense of richness in fat, or, in other words, that the yield of fat tends to constancy. The yield of milk and the percentage of fat are much more variable than the total amount of fat.

**The effect of agitation on milk separation**, T. BERG (*Nord. Mejeri. Tidn.*, 26 (1911), No. 34, p. 399; *N. Y. Produce Rev. and Amer. Cream.*, 32 (1911), No. 22, p. 808).—It was found that in a separator which did not skim milk satisfactorily the dasher of the pasteurizer had a speed of 180 revolutions per minute and the fat percentage in skim milk was 0.1. When the milk was heated in a water bath and separated the skim milk showed only 0.06 per cent fat. When the speed of the dasher in the pasteurizer was reduced to 132 revolutions the separation left 0.06 per cent of fat in the skim milk, showing that the defect could be remedied in two different ways.

**Machine-drawn v. hand-drawn milk: An inquiry into the relative bacterial content**, N. MACDONALD (*Proc. Roy. Soc. Victoria, n. ser.*, 24 (1912), No. 2, pp. 420-431).—In these tests 2 cows were milked by hand and 2 by machine, and all sources of contamination were removed as far as possible.

When the strippings of the machine-drawn milk were added to the bulk of the milk before sampling, the hand-drawn milk showed 5,000 bacteria per cubic centimeter and the machine-drawn milk 10,750 as a daily average, but during the period when no strippings were added to the machine-drawn milk the average figures were 9,500 for the hand-drawn milk and 3,500 for the machine-drawn milk. Taking the period as a whole, the average per cubic centimeter was 7,500 for hand-drawn milk and 6,750 for the machine-drawn.

It is stated that no definite conclusions could be drawn from these figures, because during the first half of the first period the average tests were much more approximate than during the second half. In addition to the ordinary lactic bacteria, cocci (particularly Staphylococci) and sarcinæ were prominent,

while Streptococci were comparatively rare. Various forms of Saccharomyces were frequently found. The colon bacillus was not common, and the liquefying bacilli present were those commonly found in water. A number of doubtful species were tested for their pathogenicity, but in no instance were the results fatal to laboratory animals, and rarely was there a passing inflammation produced.

Some of the results are summarized as follows: "Provided the apparatus of the milking machine is intelligently handled, and it is thoroughly attended to as regards cleanliness and sterilization, its use does not interfere with the general health of the cow or of the udder. The milking machine so used does not lead to a greater bacterial contamination of the milk than does the process of hand milking, even when conducted under the most approved conditions, but on the contrary the average results show an improvement."

**The Copenhagen milk supply, J. H. MONRAD** (*N. Y. Produce Rev. and Amer. Cream.*, 3½ (1912), No. 7, pp. 346, 348, 350, 352).—An account of a method of furnishing a sanitary supply of milk to Copenhagen, which has had no epidemic traceable to milk since 1901. Since 1880 the death rate of children has dropped from 219 to 119 per 1,000, due in large part it is thought to the improvement in the methods of handling milk. The translation of the text of the Copenhagen milk ordinance is given.

**Regulations governing the sale of milk in Prussia** (*Molk. Ztg. [Hildesheim]*, 26 (1912), No. 6½, pp. 1202-1205).—This contains the text of the regulations issued July, 1912, by the Minister of the Interior, Agriculture, and Public Domain.

**Milk products in the Siebenburg region of Hungary, F. BAINTRER** (*Kisérlet. Közlem.*, 15 (1912), No. 2, pp. 227-268).—This reports analytical data on cream, butter, buttermilk, cheese, and whey obtained from the milk of sheep and buffalo.

**Measuring color: An oleo standard** (*Hoard's Dairyman*, 44 (1912), No. 6, p. 131).—A report of an examination by optical methods of numerous samples of butter and oleomargarine. As the result of this work it is suggested that the latter be deemed an imitation of butter only when it contains less than 55 per cent of white.

**Parchment paper for dairy use, M. SIEGFELD** (*Molk. Ztg. [Hildesheim]*, 26 (1912), No. 60, pp. 1125, 1126).—The author reports analyses of 66 samples of parchment papers sold for wrapping dairy products. The content of water-soluble material ranged from 0.13 to 28.25 per cent, and the ash from 0.28 to 7.89 per cent. Only 23 samples could be designated as of good quality when judged by the standard advocated by Burr and Wolff (*E. S. R.*, 23, p. 616).

**Factory arrangement, F. W. CULBERTSON ET AL.** (*N. Y. Produce Rev. and Amer. Cream.*, 3½ (1912), No. 7, pp. 364, 365, figs. 3).—This contains plans of several cheese factories showing the arrangement of apparatus.

## VETERINARY MEDICINE.

**Principles of microbiology: A treatise on bacteria, fungi, and protozoa pathogenic for domesticated animals, V. A. MOORE** (*Ithaca, N. Y., 1912, pp. XI+506, figs. 101*).—This volume has been prepared as a text-book for veterinary students beginning the study of microbiology. It is said to be the outgrowth of a lecture course which accompanied laboratory work in bacteriology and protozoology. "In its preparation, the purpose has been to point out the place and rôle of micro-organisms in nature; to give the methods for their study and identification; to indicate the relation of certain species to animal diseases; to give a description of the more important species pathogenic for

animals; and a brief discussion of the reaction of the tissues to microbial invasion and the theories of immunity."

**Text-book of pathology**, J. G. ADAMI and J. McCRAE (*Philadelphia and New York, 1912, pp. X+17-759, pls. 11, figs. 304*).—This text-book, based upon the volumes previously noted (E. S. R., 24, p. 384), takes up both general (pp. 17-331), and special and systematic (pp. 333-708) pathology. Some 200 original engravings from drawings have been introduced in this work.

**Results of research in the general pathology of pathologic anatomy of man and animals**, edited by O. LUBARSCH and R. OSTERTAG (*Ergeb. Allg. Path. Mensch. u. Tierc. 15 (1912), pt. 2, pp. XV+967*).—The contents of this volume are as follows: Double Formations or Composite Monsters of Man and Animal, by H. Hübner (pp. 1-348); Storage of Glycogen in the Animal Body, by W. Klestadt (pp. 349-415); Pathology of the Thymus Gland, by J. Wiesel (pp. 416-782); Pathology of the Pancreas, by F. Albrecht (pp. 783-886); and Diseases of the Ear, by R. Panse (pp. 887-921). A voluminous bibliography in each case is appended.

**Veterinary medicine**, J. LAW (*Ithaca, N. Y., 1911, 3. ed., rev. and enl., vols. 2, pp. 597; 4, pp. 787*).—A third revised edition of these volumes (E. S. R., 13, p. 899; 14, p. 710).

**Proceedings of the American Veterinary Medical Association** (*Proc. Amer. Vet. Med. Assoc., 48 (1911), pp. 725, pls. 37, figs. 17*).—Among the more important papers presented in this report of the proceedings of the convention held at Toronto, Canada, in August, 1911, are the following: Observation on the Merits and Practicability of Resection of the Flexor Pedis Perforans Tendon, for the Relief of Open Navicular Bursa and Bayer's Operation for Quittor, by G. H. Berns (pp. 279-290); The Merits of Williams' Operation for Roaring, by F. Hobday (pp. 291-298); The Surgical Relief of Roaring, by W. L. Williams (pp. 299-317); Bacterins as an Aid in Wound Healing, by C. H. Jewell (pp. 326-335); The Cause and Treatment of Pulmonary Emphysema, by W. G. Hollingsworth (pp. 344-348); Hog Cholera Serum, by F. A. Bolser (pp. 349-361); Traumatic Pericarditis, by G. H. Roberts (pp. 362-368); The Treatment of Pneumonia and Pleurisy, by H. P. Hoskins (pp. 369-377); Intracellular Bodies Associated with Equine Anemia, by W. B. Mack (pp. 378-382); Observations Concerning the Pathology of Roup and Chicken Pox (E. S. R., 26, p. 889) by C. M. Haring and C. A. Kofoid (pp. 413-423); The Pathology of Nephritic Affections in Domesticated Animals, by K. F. Meyer (pp. 424-441); An Undescribed Pathogenic Bacterium in Milk (E. S. R., 26, p. 87), by E. C. Schroeder and W. E. Cotton (pp. 442-449); Bovine Hematuria in British Columbia (E. S. R., 26, p. 881), by S. Hadwen (pp. 450-462); The Etiology of Infectious Abortion in Live Stock (E. S. R., 26, p. 883), by E. S. Good (pp. 463-476); The Results Obtained in the Eradication of Tuberculosis from a Herd by the use of Tuberculosis Vaccine and the Bang System (E. S. R., 27, p. 382), by S. H. Gilliland (pp. 477-492); Immune Bodies and Biological Reactions (E. S. R., 26, p. 579), by A. Eichhorn (pp. 493-510); Susceptibility, Anaphylaxis and Immunity, by R. A. Archibald (pp. 511-518); Some of the Features of Sanitary Police Work as Applied in the Federal Quarantine Service (E. S. R. 27, p. 77), by R. W. Hickman (pp. 519-535); The Tuberculin Test (E. S. R., 27, p. 381), by P. Fischer (pp. 536-556); Anthrax and Tick Fever (E. S. R., 27, p. 81), by W. H. Dalrymple (pp. 557-571); The Control and Eradication of Glanders, by C. D. McGilvray (pp. 572-586); and The Sanitary Production and Handling of Commercial Milk, by C. Way (pp. 587-593).

The report of the committee on diseases includes papers on The Recurrence of Dourine in the United States, by J. R. Mohler (pp. 169-183); Foot Evil in Horses and Mules, and Sore Mouth in Dogs, by W. H. Dalrymple (pp. 183-

188); *Biologic Products Used in Veterinary Medicine*, by A. T. Kinsley (pp. 188-201); and *The Effect of Nuclein on the Blood*, by B. F. Kaupp (pp. 207-218).

**Biological investigations in regard to pregnancy.** **Diagnosis of pregnancy with the optical method and dialysis.** E. ABBERHALDEN and M. KIUTSI (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 77 (1912), No. 4, pp. 249-258; *Berlin. Tierärztl. Wehnschr.*, 28 (1912), No. 25, pp. 446, 447).—The serum of pregnant subjects is capable of cleaving peptone prepared from the placenta. This act of cleavage can be noted with the polariscope, where it causes a change in rotation within 48 hours. By utilizing this principle the author believes he has an accurate method for diagnosing pregnancy. The tests were made with humans and several animals.

The results obtained with the method were confirmed by subjecting the various sera and placentas (previously boiled to remove biuret) to dialysis. From the serum coming from a nonpregnant subject no biuret test was obtained in the diffusate. Clinical results always substantiated the laboratory findings.

**Study of the agglutinability of the various strains of *Micrococcus melitensis*,** L. NEGRE and RAYNAUD (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 15, pp. 664, 665; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, 11, Ref., 5 (1912), No. 12, p. 253).—The contradictory statements made in regard to the agglutination of *M. melitensis* led the author to study 5 strains of the organism, all from 24-hour old cultures contained in a salt solution and tested in a serum dilution of 1:30, and 37 of them human sera.

The microscopic method seemed to agree with the findings obtained by the macroscopic method. Some of the strains examined showed a marked agglutination, and agglutinated not only specific sera, but also normal sera. Other strains in the 1:30 dilution could be agglutinated only with sera which came from absolute clinical cases of Malta fever. The behavior of the individual strains seemed to be the cause for the conflicting statements which occur in the literature.

**Anaphylaxis test with anthrax bacilli,** B. BUSSON (*Ztschr. Immunitätsf. u. Expt. Ther.*, 1, Orig., 12 (1912), No. 6, pp. 671-677; *abs. in Centbl. Bakt. [etc.]*, 1, Abt., Ref., 54 (1912), No. 2, p. 59).—Anaphylaxis could not be produced against anthrax bacilli or antibodies which could be detected in vitro. Thinking that the capsule-forming property of this organism was responsible for this, the author made tests with bacilli cultivated at 42.5° C., and as a result only atypical slimy capsules were produced. Anaphylaxis could be produced by these organisms in rabbits in so far that the rabbits showed an increase in temperature after the infection.

**The precipitin reaction and anthrax in hogs,** W. PFEILER (*Berlin. Tierärztl. Wehnschr.*, 28 (1912), No. 25, pp. 463-466).—The results of this work showed that even when conditions seemed different than those usually observed the diagnosis of anthrax in pigs could be substantiated by the precipitin reaction. Very often when negative cases are reported with the positive material some experimental error has crept into the process.

**Aggressin immunization against blackleg,** O. SCHÖBL (*Centbl. Bakt. [etc.]*, 1, Abt., Orig., 62 (1912), No. 3-4, pp. 296-304).—Previously noted from another source (E. S. R., 27, p. 80).

**The milk from cows affected with foot-and-mouth disease,** H. BERTIN-SANS and E. GAUJOUX (*Rec. Gén. Lait*, 9 (1912), No. 7, pp. 145-151).—This is a study of the milk obtained from 10 cows suffering from foot-and-mouth disease and comprises the determination of the freezing point, acidity, catalase, and reductase.

It was found that the catalytic power was increased at the beginning of the disease and later returned to normal, so that this is to a certain measure an indication of the gravity of the condition. The reducing power (reductase) was determined by the authors' method, i. e., an aqueous solution of methylene blue 1:40, and an aqueous alcoholic solution of fuchsin 1:4,000. In most of the cases the reducing time was 3 hours or over at the outset and did not vary very much during the course of the disease, but in some instances the reduction time was lessened at the outset, though afterward increasing, and taking as a rule more than 3 hours.

The significance of the agglutination-complement fixation and the conjunctival test for the diagnosis of glanders. H. MIESSNER (*Centbl. Bakt. [etc.]*, 1. Abt., *Orig.*, 63 (1912), No. 4-6, pp. 482-542, figs. 6).—The height of the agglutination titer and complement-fixing values of the serum of glandered animals stands in direct relation to the age of the pathologic process but not to its extent. The author does not consider fixing values of 0.3 and 0.4 for the serum of horses in stables free from glanders to be suspicious, but does when found for the serum from animals in infected barns. It is also advisable to make the second or third tests 10 days apart.

The conjunctival test was used with 133 horses, among which were 59 clinically affected with glanders. Of these 59, 53 showed a positive ophthalmic test while none of the 74 horses classed as sound reacted. With the conjunctival test a reaction can be completed within from 14 to 20 hours after instilling the mallein, and when in doubt as to the results the test can be repeated within 24 hours and with the same eye.

A comparative study with the agglutination, conjunctival, and complement fixation tests was made with 74 horses for the purpose of determining the value of the tests. With the first named test 88.8 per cent of the horses which were positively glandered were detected; with the complement fixation method 100 per cent; and with the conjunctival test 94.4 per cent. With the last two methods no sound horses were diagnosed as being glandered.

A previous conjunctival-mallein test has no influence upon a subsequent agglutination test, although it seems to increase slightly the complement fixation values. The agglutination, complement fixation, and ophthalmic tests were studied with horses artificially infected per os and subcutaneously. The conjunctival reaction was noted from 5 to 9 days after infection, the agglutination test in from 5 to 7 days, and the complement fixation test in from 10 to 14 days after infection. Agglutination or complement-fixing bodies are not transmitted by the mother to the fetus.

Critical investigation in regard to the diagnostic value of the ophthalmic reaction in glanders, E. FRÖHNER (*Monatsh. Prakt. Tierheilk.*, 28 (1911), No. 1, pp. 1-35; *abs. in Hyg. Rundschau*, 22 (1912), No. 11, p. 711).—The ophthalmic reaction was found very valuable for diagnosing glanders in horses. It was tested with 21 animals, which were undoubtedly glanderous, at the internal clinic of the veterinary high school at Berlin. The method was conducted by instilling from 1 to 2 drops of a mallein solution (0.05 gm. of mallein siccum [Foth] in 4.5 cc. of a 0.5 per cent solution of carbolic acid). After 12 hours a pronounced, thick purulent secretion was produced, which is not obtained with sound horses.

Experimental therapy of Rocky Mountain spotted fever, P. G. HEINEMANN and J. J. MOORE (*Jour. Infect. Diseases*, 10 (1912), No. 3, pp. 294-304).—“Horses are susceptible to spotted fever if the virus of guinea pigs is injected subcutaneously and intravenously. The fever usually takes a mild course and the temperature is not exceedingly high. Normal temperature appears again

after 7 to 9 days. It would be interesting to allow infected ticks to bite horses and determine whether the disease can be communicated that way.

"The serum from horses recovered from spotted fever has protective value. The potency is largest after about 12 days from the time of the reappearance of normal temperature.

"Repeated injection of spotted fever virus increases the potency of the serum materially, but does not produce a second attack of spotted fever.

"One cc. immune horse serum protects guinea pigs injected with spotted fever virus up to, and including, the first day of high temperature. If serum is given later there is no protection.

"Treatment of guinea pigs, injected with spotted fever virus, with sodium cacodylate and repeated every day, commencing with the first appearance of temperature, has no effect on the course of the disease."

Methods of exterminating the Texas-fever tick, H. W. GRAYBILL (*U. S. Dept. Agr., Farmers' Bul. 498, pp. 42, figs. 19*).—This paper is a revision of Farmers' Bulletin 378 (E. S. R., 22, p. 163).

In regard to the origin and development of general tuberculosis, A. JURGELUNAS (*Ztschr. Hyg. u. Infektionskrankh., 78 (1912), No. 2, pp. 307-366*).—The conclusion reached by this author is that tubercle bacilli of human and bovine origin are simply varieties of the same organism.

Guinea pigs which were allowed to inhale dry and ordinary cultures of the human type of bacillus first showed the infection in the organs contained in the thoracic cavity. If, however, the animals were given an emulsion of the bacilli by way of the mouth the organisms passed quickest and easiest through the walls of the mouth and tracheal cavities.

The introduction of the human type of bacillus into the alimentary tract of rabbits in many instances did not cause tuberculosis, whereas bovine tubercle bacilli when given in this manner produced the disease very easily. Cultures of the human type of tubercle bacillus, when fed to suckling pigs, goats and sheep, produced no disease in these animals, while feeding the bovine type will produce tuberculosis. The best subjects for diagnosing the type of tubercle bacillus present in a given case are the rabbit and suckling pig.

Investigation in regard to the normal temperature of healthy and tuberculous rabbits as well as the local and general specific capacity of tuberculous rabbits to react towards tuberculin preparations, O. RASCHKE (*Untersuchungen über die Normaltemperatur gesunder und tuberculöser Kaninchen, sowie über die örtliche und allgemeine spezifische Reaktionsfähigkeit tuberculöser Kaninchen auf Tuberkulinpräparate. Inaug. Diss., Univ., Leipzig, 1911, pp. 66*).—The temperature of healthy and artificially infected rabbits was found to fluctuate between 38.8 and 40.1° C., and in about 80 per cent of the animals examined between 39.2 and 39.7°. The ophthalmic reaction, cutaneous reaction, intradermal reaction, and local subcutaneous reaction conducted with phymatin bovis (Klimmer) yielded a large percentage of negative results and can therefore not be considered of any practical value for diagnosing tuberculosis in rabbits. The subcutaneous thermal reaction on the other hand was found to be satisfactory in doses of from 0.025 to 0.25 cc.

A bibliography of 50 titles is appended.

Tuberculosis in man and animal, A. WEBER (*Centbl. Bakt. [etc.], 1. Abt., Orig., 64 (1912), Festschrift F. Loeffler, pp. 243-265*).—A critical review of work done in regard to the communicability of tuberculosis from animal to man.

The conclusion reached is that the bovine type of bacillus when compared with the human type plays only a secondary part as far as tuberculosis in man is concerned. Precautionary methods must therefore be directed primarily to preventing the transference of the disease from man to man.

The intradermal test for tuberculosis, F. W. PORTER (*Amer. Vet. Rev.*, 41 (1912), No. 4, pp. 463-465).—After pointing out the difficulties encountered with the thermal method of testing, the author reports his results of a comparative study between the thermal and intradermal tests. "Of the 60 head tested by the intradermal method, all of which had reacted to the thermal test, 27 did not react to the intradermal test. Of this 27, 6 were considered as not clearly marked either way."

Antituberculosis serum, A. CALMETTE (*Bul. Inst. Pasteur*, 10 (1912), No. 5, pp. 193-204).—This is a general review of the work done in regard to antisera for tuberculosis. It deals with the following sera: Maragliano, Marmorek, S. Arloing and L. Guinard, Lannelongue, Archard and Gaillard, Vallée, Jousset, Ruppel and Richman, Bruschetti, and Rappin. The mode of action of the sera is discussed critically.

The relation of barium to the loco-weed disease (*U. S. Dept. Agr., Bur. Plant Indus. Bul.* 246, pp. 67, figs. 15).—In a previous publication of the Department (*E. S. R.*, 20, p. 280) barium was held responsible for the symptoms of loco poisoning. This has led to subsequent investigations, which are summarized below:

*A field study on the relation of barium to the loco-weed disease*, C. D. Marsh (pp. 7-37, figs. 15).—In order to confirm the previous conclusions, the author has carried on feeding experiments with horses and cattle to determine the possibility of preventing the disease, and he states that if barium is the cause of loco poisoning, sulphates would form a logical antidote. Experimental administration of magnesium sulphate and sulphuric acid fed in amounts much greater than necessary to neutralize the barium had no antidotal effect. Experimental feeding of barium salts produced symptoms which corresponded in general to those recorded in literature in acute poisoning, but without marked cumulative effect or acquired tolerance. The post-mortem appearances corresponded to those recorded in acute poisoning. The symptoms and pathology of barium poisoning were found to differ in a marked degree from those noted in loco poisoning. The author believes that typical loco poisoning is not produced by barium feeding alone.

*Laboratory studies on the relation of barium to the loco-weed disease*, C. L. Alsberg and O. F. Black (pp. 39-61).—The authors have carried on laboratory studies of a large number of plants to determine the action of barium in loco-weed disease, particularly as connected with the possibility that plants may under certain conditions derive harmful constituents from the soil.

They conclude from their experiments with laboratory animals that the etiological factor in loco weeds which is responsible for the toxicity of these plants in laboratory experiments is not barium. This conclusion is based on the fact that many plants from the Western States contain barium, but there is no evidence that such plants injure stock upon the range. Plants in certain sections of Virginia were found to contain barium in quantities that are of the same order of magnitude as in loco plants, but there was no evidence that such plants injure stock. In dried loco plants barium is contained in an almost insoluble form. Extracts prepared by digesting with artificial gastric and pancreatic juices contained but slight traces of barium, but, nevertheless, it is claimed that large doses of these may be toxic. There were usually found enough salts of calcium, potassium, and metals other than barium in the extract of 250 gm. of dried loco plant to account for the death of rabbits. Similar extracts of alfalfa may also cause death of rabbits in similar doses. Acetic-acid extracts of the ash of such barium-yielding plants from the Western States as were examined contained but minute traces of barium.

Investigations of the etiology of infectious abortion of cows and mares, E. S. Good (*Kentucky Sta. Bul.* 165, pp. 227-229, pls. 13).—The first part of

this bulletin (pp. 231-279) deals with infectious abortion of cows; the second part (pp. 280-296) with infectious abortion of mares.

This laboratory has isolated the germ of infectious abortion (*Bacillus abortus*) in 10 cases from 3 herds of aborting cows in Kentucky, 3 of which were from the internal organs of the fetus. "In one instance we secured a growth of this bacillus from the blood of the liver, kidneys, and umbilicus, and from the contents of the stomach and large and small intestines of the fetus. There were instances in which we were able to find this germ in the afterbirth and stomach of the fetus, but unable to secure a growth of the organism.

"Methods of isolation as well as the physiological, morphological, and cultural characteristics of this germ, together with illustrations of the same are given in this bulletin.

"The bacillus causing the disease of infectious abortion in cows has not as yet been isolated from the uterine exudate of aborting mares by this laboratory, nor as far as we know by any other laboratory. A bacillus belonging to the subgroup II, or intermediate group, of the colon-typhoid group (to which subgroup belong such pathogenic organisms as *Bacillus enteritidis* and *B. cholerae-suis*) has been isolated by this laboratory from the afterbirth, the uteruses and the internal organs of fetuses, of 2 studs of aborting mares, and 1 stud of aborting jennets. In 2 instances the *B. coli communis* was found in large numbers in the fetal membranes of mares aborting in the early stages of gestation. The pathological changes in the afterbirth and internal organs of fetuses of aborting mares are much more marked than is the case with aborting cows."

A bibliography is appended.

Investigations of infectious abortion, E. S. GOOD (*Amer. Jour. Vet. Med.*, 7 (1912), No. 4, pp. 121-124).—This paper relates to the investigations noted above.

With regard to the pathological changes in the internal organs of fetuses of aborting mares, "at times there are small ulcers about 1 mm. in diameter on the top of the auricles of the heart of a fetus of an aborting mare. The spleen is enlarged and thickly studded with petechia on its surface. The mesenteric lymphatic system is highly congested; the ovaries and uterus of a female fetus and testicles of a male fetus are usually much enlarged and hemorrhagic."

The diagnosis of infectious abortion in cattle, F. M. SURFACE (*Kentucky Sta. Bul.* 166, pp. 303-365, pl. 1, figs. 4).—This is a study of the comparative value of the agglutination and complement fixation tests for detecting animals which are infected with the *Bacillus abortus*. In all there were 576 animals tested, out of which 44.8 per cent gave a positive reaction. In 4 herds, comprising 151 cows, 23.1 per cent aborted a year previous to the test (only cows which had terminated at least 1 pregnancy being considered but including heifers which had aborted their first calves), and 56.3 per cent showed a reaction. Among the cows which aborted, 85.7 per cent showed a reaction, while in 3 of the herds 90 per cent or more of the aborting cows reacted to the tests. Of all the aborting cows only 3.3 per cent failed to show a reaction.

In general there was a close agreement between the agglutination and complement fixation tests, and in the majority of cases where there was no agglutination there was no complement binding. A small number of animals showed no complement fixation but agglutinated in dilutions of 1:20. Agglutinations of 1:100 are regarded by the author as practically specific, but in the tables shown many of the cows agglutinated in dilutions of 1:50 or 1:20. The agglutination test, therefore, should not be relied upon alone.

The bulletin includes a detailed statement of the technique of conducting both of these tests, a general description of the etiology, bacteriology, symptoms, etc., of the disease, and some practical suggestions for combating this condition.

The diagnosis of contagious abortion in cattle by means of the complement fixation test, F. B. HADLEY and B. A. BEACH (*Wisconsin Sta. Research Bul.* 24, pp. 217-248, pls. 4, figs. 2).—This bulletin concerns itself chiefly with the diagnostic methods for this disease, especially the complement fixation or binding method. To determine the practicability of the complement fixation test, the technique of which is described in detail, tests were carried out with the sera obtained from about 500 animals. These animals were distributed in widely separated herds, and were considered representative of the Wisconsin dairy industry.

"The accuracy of this method of diagnosis is as great as any method based upon a biological reaction. Further experimentation may perhaps suggest some modification of the present technique. Where large numbers of animals are to be tested, such changes would be acceptable if not made at the expense of accuracy. However, at present we find it quite possible to run tests on 50 or more animals a day without undue exertion.

"The test affords a reliable means by which infected animals may be detected. Proper methods of isolation and control may then be instituted by which the disease can be prevented from spreading to noninfected cows and heifers. It is a qualitative and not a quantitative test and simply indicates the presence or absence of the specific immune bodies; but clinical history has so closely corroborated the test that we may assume it to be a reliable guide as to the presence or absence of the abortion bacilli."

In order to determine if the test was rigidly accurate some additional experiments were made with the station herd, which included heifers unavoidably exposed to the infection and cows which were known to have aborted. The test detected infected animals a long time before they aborted. It furthermore showed that immune bodies were present longer than a year in some animals and that they gradually disappeared in other cases. In the case of 1 calf, which had dropped prematurely and was in constant association with infected animals, the animal did not show immune bodies up to the time when she was a year old. The serum of a herd bull, which associated with an infected cow, gave a positive reaction. Bacteriological examinations of 20 placental membranes were made with a result that 13 were found to contain the abortion bacillus.

"The interpretation of the reaction may be summarized as follows: (1) Cattle in which the serum shows a complete fixation of the complement in quantities of 0.01 cc. and 0.02 cc. are or have been infected with abortion bacilli. (2) Cattle in which the serum gives a complete complement fixation in the quantity of 0.02 cc. and an incomplete fixation in 0.01 cc. amount, also are or have been infected with the abortion bacilli. (3) Cattle in which 0.01 cc. of the serum shows no binding while the larger quantity gives an incomplete binding should be considered questionable reactors and retested after 4 to 6 weeks. (4) Cattle in which the serum shows no power of fixing the complement in either amount should be considered free from the infection."

Freezing was not found to kill the organism, strongly binding antigens being later prepared from the frozen strains, which were recovered in pure cultures.

Some field experiments with the test are also reported.

Immunizing tests in infectious intestinal catarrh, MIESSNER and KOHLSTOCK (*Berlin, Tierärztl. Wchnschr.*, 28 (1912), No. 25, pp. 450-452).—The material obtained by scraping the intestinal mucus membranes of bovines infected with intestinal catarrh was rubbed up into a paste with comminuted mesenteric lymph glands in a mortar. A 20 per cent solution of antiformin was then added, stirring constantly during the process, the mixture transferred to a 10 to 20 liter flask, and the flask with its contents shaken for 2 days in a shaking device. The emulsion so produced was filtered and the filtrate centrifuged.

The sediment obtained, which consisted of practically only acid-fast bacilli, was dried in a Heim-Faust apparatus. The dried pulverent material was termed "enteritidin" by the authors. Sero-diagnostic tests with "enteritidin," using a suspension of this preparation as an antigen for the complement fixation method, resulted negatively with the serum obtained from cows having infectious intestinal catarrh.

In order to test the therapeutic value of the preparation 2 calves (Nos. 5 and 7) were given 100 mg. in a physiological salt solution intravenously. Two other animals, one sound (No. 6) and the other (No. 122) having an infectious catarrh of the entire alimentary tract, were given 100 mg. per os. Calf No. 6 was killed after 3 months' time and found to have a chronic intestinal catarrh. Calf No. 5 was destroyed 10 months after the injection, and although the mucosa of the alimentary tract seemed to be somewhat thickened no acid-fast bacilli could be detected in the mesenteric lymph nodes. A few organisms were found in the mucosa of the small intestine after an extended search. One year after the infection calf No. 7 was killed, but no bacilli could be detected in either the mucous membranes or in the mesenteric lymphatic glands, although when subjecting the tissues to the action of antiformin a few bacilli were noted. Three other animals, one infected and two healthy, were vaccinated intravenously with 100 mg. of the preparation, but these tests are not completed.

Some tests on the transference of infectious intestinal catarrh from mother to offspring through the agency of feces were also included, which show that without doubt the disease can be acquired during the suckling period.

In regard to sheep pox in Tunis and the attenuation of the virus by heating, E. DUCLOUX (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 7, pp. 279-281; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 53 (1912), No. 8, p. 238).—Sheep pox is enzootic in North Africa and causes many deaths among sheep, chiefly young sheep, during the rainy season. An attenuated vaccine which will produce the disease only at the site of injection can be prepared by heating virus in a water bath. All sheep intended for export were formerly treated with antipox serum.

Experimental investigations in regard to hog cholera, P. UHLENHUTH (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 64 (1912), *Festschrift F. Loeffler*, pp. 151-165).—This is a critical review of work done on hog cholera under the direction of the author at the Institute of the Royal Health Department at Berlin. A comparison was made with the work of other investigators.

Hog cholera, C. D. MCGILVRAY (*Amer. Vet. Rev.*, 41 (1912), No. 4, pp. 444-449).—An outbreak occurred at Kenora, Manitoba, which involved 146 hogs. All of the animals were slaughtered. The results of the investigation in regard to the source of the disease furnished strong circumstantial evidence in support of the belief that it started by feeding uncooked swill or kitchen refuse which contained pork or pork products.

A preliminary report on the action of china berries, leaves, and blooms on pigs, C. A. CARY (*Amer. Vet. Rev.*, 41 (1912), No. 4, p. 455).—Preliminary tests of the action on pigs of these materials have led to the following conclusions:

"The berries, leaves, and blooms all produce intoxication in pigs. Somewhat prolonged feeding of the berries will produce distinct fatty degeneration of the kidneys and liver. There are other changes, but these are the most prominent."

Helminthes parasitic in equines, R. T. LÆIPER (*Vet. Jour.*, 68 (1912), No. 446, pp. 469-472).—This is a classified list of the nematodes, trematodes, and cestodes parasitic in equines, including 56 species representing 12 families and 17 genera.

Studies on fowl cholera.—II, The rôle of a homologous culture of slight virulence in the production of active immunity in rabbits, P. B. HADLEY

(*Rhode Island Sta. Bul. 150, pp. 81-161*).—This continues work previously noted (E. S. R., 26, p. 185).

"Among 10 different strains of the fowl cholera bacterium investigated for their resistance-producing power, one (culture 52) was discovered which was capable of producing perfect immunity in rabbits to highly virulent cultures; this immunity was secured by means of subcutaneous, intravenous, and also intraperitoneal inoculations. That the resistance in question was not a local, or 'zonal,' immunity, was shown by inoculating previously protected rabbits in the ear, flank, or back, also by intravenous and intraperitoneal inoculations, none of which were fatal. The smallest amount of culture 52 yet used to produce immunity in rabbits is 0,000,000,01 cc.; but amounts as large as 3 cc. were tolerated, and gave similar results. Smaller amounts would, in all probability, also afford resistance. The resistance produced by inoculation with culture 52 was sufficiently strong to protect against at least 2 cc. of virulent culture when the M. L. D. [minimum lethal dose] of the latter was 0,000,000,000,000,000,000,01 (one-hundredquintillionth) cc.

"In protectively inoculated rabbits a slight resistance was manifested within 2 to 4 days, but complete immunity did not appear until the seventh day after the inoculation with culture 52. Complete immunity to the virulent culture (48) has been found to endure in protected rabbits for at least 10 months; it is, in all probability, permanently acquired. The simultaneous inoculation of culture 52 (amounts from 0.001 cc. to 1 cc.) and culture 48 (0.001) proved fatal in all cases; but the inoculation of 0.5 cc. of culture 52 prevented a fatal termination when inoculated simultaneously with 0,000,000,001 cc. of culture 48. Attempts to produce resistance in rabbits by the inoculation of dead or attenuated (by heating) cultures of strains 52 and 48 have thus far failed, except with repeated inoculation of 52. Immunity to culture 48 is inherited: Does, 6 to 7 months after their protective inoculation, have given birth to young possessing, at the age of 30 days, complete resistance to 0.01 cc. of the virulent culture; but no cases have been met with in which the young, at the age of 60 days, were still immune.

"The natural resistance possessed by guinea pigs to the fowl cholera organism can be so raised by subcutaneous inoculation with culture 52, that both subcutaneous and intraperitoneal inoculations with the virulent culture (48) are easily tolerated. Although gray rats are susceptible to fowl cholera, the strain of white rats used in this investigation possessed a high degree of natural immunity. In a few preliminary tests a moderate degree of resistance in pigeons and fowls to a virulent culture of the fowl cholera bacterium has been produced by intramuscular, and (more successfully) by subcutaneous, inoculations with culture 52; but this method, for birds, is as yet somewhat less reliable than for rabbits. Inoculation with culture 52 has been found to protect rabbits, not against virulent culture 48 alone, but also against the only other (three) highly virulent cultures obtainable at the present time. In two cases, as the result of a single subcutaneous inoculation with 0.5 cc. and 1 cc., respectively, of serum, derived from an actively immunized rabbit, 9 months after immunization, the fatal issue in the infected rabbits was delayed from 14 hours (control) to 4 and 5 days, respectively. Many of the phenomena observed in this study make it appear that the immunity being considered is an aggressin immunity in the sense in which this term is employed by Bail, Weil, and others. But the observation that various attenuated cultures, all of which possess about the same ability to grow at the point of inoculation (implying, according to this theory, approximately equal 'aggressiveness') demonstrate by no means equal resistance-producing powers, suggests that the aggressins and 'anti-aggressins' do not wholly explain the production of immunity in these cases. These inves-

tigations are being continued with special reference to (1) the production of active immunity in birds; and (2) the production of passive immunity in rabbits."

A bibliography is appended.

**Primary principles in the prevention and treatment of disease in poultry,** G. B. MORSE (*U. S. Dept. Agr. Yearbook 1911, pp. 177-192*).—The object of this paper is to impress poultry raisers with the importance of cleanliness in maintaining the health of poultry. The 7 primary principles outlined in the paper previously noted (*E. S. R., 24, p. 188*) are emphasized.

## RURAL ENGINEERING.

**Irrigation investigations,** G. E. P. SMITH and F. C. KELTON (*Arizona Sta. Rpt. 1911, pp. 566-572, fig. 1*).—Hydrographic investigations in the Sulphur Springs, Kilito, and Santa Cruz valleys, carried on in cooperation with the U. S. Geological Survey, are reported giving river discharge data, and data relative to pumping plants and ground waters in the districts. A discussion of the application of the doctrine of priority in the use of underground waters is appended, the following conclusions being drawn:

"Priority in an underflow appropriation, then, ought not to be positive as it is in the case of surface streams, but should be subject to limitations as follows: (1) Any injury or interference must be proven clearly. (2) The injury must be considerable. Trivial injury, or slight injury at infrequent or short periods should not be cause for action. (3) A ditch owner must be reasonably willing to cooperate with his neighbors in the general development of the underflow. (4) A ditch owner must maintain his collecting head or flume in good condition as an efficient agent for taking and carrying water."

**Measurement and distribution of irrigation water,** L. M. WINSOR (*Utah Sta. Circ. 6, pp. 19-38, figs. 4*).—This circular gives the requirements for the construction and installation of the Cippoletti trapezoidal weir with complete end and bottom contractions and sharp crests, and gives directions and tables for its use in the measurement and division of irrigation water. Brief discussions are also given of time, division of water, and of the duty of water, with a few definitions and hints to aid the irrigator.

**Possibilities and need of supplemental irrigation in the humid region,** M. B. WILLIAMS (*U. S. Dept. Agr. Yearbook 1911, pp. 309-320, pls. 2*).—In treating this subject the author gives a brief historical note on the practice of irrigation in the United States, points out the relation of rainfall to irrigation, together with the importance of supplemental irrigation, and describes the possibilities and advantages of irrigation in the North Central, North Atlantic, and Southern States. In addition to the methods of irrigation adapted to the humid region and including surface irrigation, subsurface irrigation, and spray irrigation are briefly noted, and the possibilities and need of irrigation east of the Mississippi are pointed out.

**Helping out the rainfall,** A. C. TRUE (*Pop. Mechanics, 17 (1912), No. 4, pp. 521-528, figs. 10*).—This article deals with the value of irrigation as a supplement to rainfall in regions suffering from droughts between wet seasons, and discusses irrigation works and their benefits to general farming and truck gardening in the Eastern and Southern States.

**The present outlook for irrigation farming,** C. S. SCOFIELD (*U. S. Dept. Agr. Yearbook 1911, pp. 371-382*).—Although irrigation farming has become only recently an appreciable factor in American agriculture, the area has nearly doubled in the last decade, there being 14,000,000 acres of irrigated land in the United States at the time of the last census. The author finds that (1) the price of irrigated land in the West is generally increasing, so that much of

the colonization is based on a prospective rise in land values rather than on prospective crop production; (2) the cost of producing irrigated crops is generally greater than that of unirrigated crops, a fact not fully realized by many prospective settlers; (3) irrigated sections must usually pass through a period of economic depression resulting from the production of crops in excess of local demands.

Irrigation farming has, however, some distinct economic advantages, many of the lands being in the midst of range lands or near large mining enterprises or centers of trade, and others in a mild climate and long growing season which permit the production of crops that do not thrive elsewhere in this country. The author believes that the prosperity of irrigated land will depend upon development along one or more of the following lines: "(1) Diversification of crops and development of local industries to such an extent that the raw crop products are largely consumed locally; (2) the production of special crops that can not be grown as well under rainfall or that may be sent to market in seasons when they are not available elsewhere; or (3) the production of larger crops of such high-priced products as can bear the cost of transportation to the general markets of the country."

Methods and cost of making subdivision on topographical survey for Sunnyside unit, Yakima project, U. S. Reclamation Service, W. E. WHITTIER (*Engin. and Contract.*, 37 (1912), No. 24, pp. 669-674, figs. 2).—A complete discussion of the resurvey, revision, and extension of the distribution system of this project, containing about 102,000 acres.

Irrigation and reclamation, S. MCINTOSH (*Jour. Dept. Agr. So. Aust.*, 15 (1912), No. 8, pp. 806-813).—A brief outline of the history of irrigation in South Australia with a list of the existing and prospective irrigation and reclamation areas.

Triennial irrigation revenue report of the Bombay Presidency (excluding Sind) for the triennium ending 1910-11 (*Trien. Irrig. Rev. Rpt. Bombay Pres.*, 1910-11, pp. IV+145, pls. 3).—This report contains statistical information, compares the results of successful triennial periods, shows the progress of irrigation works, and gives a detailed list of the works.

Economic value of drainage, A. D. WILSON (*Farmer*, 31 (1912), No. 25, p. 835, fig. 1).—The author gives figures to show that tile drains, if properly and permanently constructed, will pay back the principal and interest on an average acre in 5 years. In this connection he discusses the requirements of a good outlet, available capital, and competent engineering services.

Construction and maintenance of open ditches, G. P. SMITH (*Proc. Iowa Engin. Soc.*, 24 (1912), pp. 89-93).—The proper construction and subsequent maintenance of open drainage ditches are dealt with, emphasizing the need of correct design and location, with special reference to cross section and grade, and of careful construction with respect to side slopes, berms, and waste banks.

Ditching by horsepower, J. C. SCHEID (*Ind. Farmer*, 67 (1912), No. 26, p. 1).—These are notes as to the work done by a horsepower ditching machine for tile drainage. It is stated that an average of 300 rods of ditch can be cut in a day and 75 rods of tile laid, at an average cost of from 3 to 3½ cts. per rod for both operations, thereby effecting a saving of from 15 to 20 cts. per rod as compared with contract work.

Some experiments with the curing of tile, G. P. DIECKMANN (*Cement and Engin. News*, 24 (1912), No. 7, p. 207).—The results of a series of experiments to determine the best method of curing cement tile are given, the experiments being made on machine-made tile 8 by 12 in. by 1 in. thick, having an average weight of 24 lbs., the mixture being 1 part cement to 3½ parts sand. The tile were subjected to different treatments, such as curing in air, immersion in hot and cold water for various periods, and steam curing under varying pressures

and for different time periods, and each tile after curing was subjected to the pressure test.

The conclusions from the experiments were as follows: The curing of tile in exhaust or moisture steam for 36 or 48 hours respectively gives the best results, after which no sprinkling or wetting is necessary; 8-in. tile, cured in exhaust steam for 3 days, tested 2,000 lbs. after being 7 days old, showing that two-thirds of the total strength can be developed in 7 days, the highest crushing strength obtained being 3,000 lbs. The curing of tile in air alone is unsatisfactory, although it is materially helped by sprinkling.

How the engineer may help to prevent troubles from defective drain tile, A. O. ANDERSON (*Engin. and Contract.*, 37 (1912), No. 25, pp. 705, 706).—A prevailing neglect among drainage engineers is claimed as to the testing of drain tile and in the making of strict specifications for their strength and the materials of their manufacture. The importance of careful design of tile lines is pointed out, and the general principles of earth pressure in their connection with the size and thickness of tile is discussed. The formula for tile design  $T = \sqrt{\frac{RSF}{12M}}$ ,

in which  $T$ =the thickness in inches,  $R$ =radius in inches,  $S$ =the load in pounds per foot,  $F$ =factor of safety for earth pressure, and  $M$ =the modulus of rupture in tile in pounds per square inch as determined by test, is presented.

A summary is given of the duties of the engineer relative to computing and specifying the depth and width of ditch, allowable loading, modulus of rupture, thickness, absorption, and materials of manufacture for the different sizes of the tile in a drainage system.

Assessment of benefits in drainage districts, I. W. HOFFMANN (*Proc. Iowa Engin. Soc.*, 24 (1912), pp. 78-80).—The author points out certain factors to be considered in making drainage district assessments, such as the kind of land, such as swamp, wet, low, and high, the distance of the different tracts from the proposed drain, the elevation of each tract above its drainage outlet, and actual tile benefits from laterals.

Supplemental report on Nelson Avenue experimental road, and report of experiments in binding gravel and crushed gravel with tar and asphalt, and also in constructing a waterbound road of gravel, J. C. WONDERS (*Ohio Highway Dept. Bul.* 13, 1910, pp. 19, figs. 17).

The physical testing of rock for road building, including the methods used and the results obtained, A. T. GOLDBECK and F. H. JACKSON, JR. (*U. S. Dept. Agr., Office Pub. Roads Bul.* 44, pp. 96, figs. 20).—This bulletin, in part a revision of Bulletin 79 of the Bureau of Chemistry, previously noted (*E. S. R.*, 15, p. 826), discusses the agencies destructive of roads and the necessary physical and mechanical qualities of the road materials, describes in detail the physical tests of road material as conducted in the Office of Public Roads, which include the hardness, toughness, impact, abrasion, cementation, specific gravity, and absorption tests, and briefly interprets the results of these tests in general on trap, limestone, dolomite, granite, sandstone, chert, gneiss, schist, slate, marble, and quartzite. As an appendix a large amount of data is given of the results of physical tests made on rock samples classified according to their location and showing availability and character of the materials as far as they have been tested throughout the United States.

Making better country roads, C. W. BUSH (*Wis. Country Mag.*, 5 (1911), No. 11, pp. 437-439, figs. 2).—The claim is presented that macadam, telford, and dirt roads are the best country roads, and brief directions for their proper construction and maintenance are given.

Effect of country roads (*Missouri Bd. Agr. Mo. Bul.*, 10 (1912), No. 5, pp. 60, figs. 24).—This bulletin points out the social and commercial advantages of

good roads to rural life in Missouri, deals with general road administration, and discusses the tractive resistance of roads in its relation to height of wheel, width of tire, and general form of wagon, indicating that 6 in. is the best width of tire for a combination farm and road wagon, and that the best form of all-round farm wagon is one with axles of equal length, broad tires, front wheels from 30 to 36 in. high, and rear wheels from 40 to 44 in. high.

**Final report on the work of the highway division of the Maryland Geological Survey, 1898-1910.** W. B. CLARK (*Md. Geol. Survey [Rpt.]*, 9 (1911), pp. 81-96).—This report briefly reviews the condition of roads in the State and the best means for improving them, the classification and distribution of road building materials of the several counties, road surveys for the preparation of plans and cost estimates of road improvement, free technical advice to towns and counties, and the state aid highway law, and gives a summarized financial statement.

**Fourth and final report on state highway construction.** W. W. CROSBY (*Md. Geol. Survey [Rpt.]*, 9 (1911), pp. 97-120).—A report on the physical and financial conditions of roads in Maryland from 1898 to 1910, including tabulated data of road mileage and cost. During the 12 years, the total expenditure on highway improvement and construction amounted to \$506,342.04.

**Highway construction in the State of Washington by convict labor.** F. A. KITTREDGE (*Engin. and Contract.*, 37 (1912), No. 26, pp. 722-726, figs. 18).—This article notes that convict labor is being used to great economic advantage in Washington on highway construction, and describes in detail the construction of a rock road on the Columbia River. A cost estimate is given showing a saving of \$82,264.84, or \$3.69 per day per man, through the use of convict labor.

**State control of highway bridge construction** (*Engin. News*, 67 (1912), No. 24, pp. 1137, 1138).—Attention is called to the frequent incompetency among county highway commissioners for letting highway bridge contracts and overseeing construction, pointing out the evils of the present system, employed more especially in the middle western States, of leaving design, specifications, contract, and construction entirely to the contractor, and noting the aversion of the average county commissioner to incurring the additional expense of employing a competent engineer. As a remedy, the plan is advocated of supervision by state engineer's office of all highway bridge design and construction.

**The agricultural motor contest at Chelles.** L. FOURNIER and L. W. ELLIS (*Sci. Amer. Sup.*, 73 (1912), No. 1904, pp. 407-411, figs. 14).—This is a comparison of European and American machines, giving a description of each machine and general conclusions as to their good and bad points, and indicating the advantages of the endless chain as a traction mechanism.

**Manure spreader with moving box bottom** (*Maschinen Ztg.*, 10 (1912), No. 11, pp. 130, 131, figs. 5).—A description of a manure spreader which has rotating parts in the box bottom which shake up the manure and pass it down to a grating below, through which it is pressed to be scattered over the field by flapping boards. This machine presents the advantages of simplicity in its working parts, making it easy to dismantle and clean, and durability, as its principal working parts and bearings are forged steel instead of castings.

**The first electric plow in Spain.** R. GOIZUETA (*Prog. Agr. y Pecuario*, 18 (1912), No. 771, pp. 275-279, figs. 5).—An electric plowing system is described consisting of a transmission line, 2 transformers, 2 motor cars, and a balance-plow operated by motor-driven windlasses on the motor cars. The cars advance for each new furrow. The current is supplied at 10,000 volts pressure and is reduced by the transformers to 750 volts for distribution.

**Motor-driven grubbing machines** (*Bl. Zuckerrübenbau*, 19 (1912), No. 9, pp. 140-143).—A general discussion of the use of animal, steam, electric, and internal combustion engine power in agriculture, favoring the last, is followed

by a description and the results of trials of 3 gas engine-driven grubbers for use in sugar-beet cultivation. Each of these is said to present a good combination of stationary and portable motors for general farm use, and in spite of rain and heavy soil gave fair satisfaction in the trials.

**A new way to handle corn fodder**, T. F. WILLOUGHBY (*Weekly Impl. Trade Jour.*, 26 (1912), No. 27, pp. 24, 26, figs. 2).—An account is given of the use of a hay press for baling corn fodder direct from the shock, in a case in which a corn shredder was not available. On opening the bales the fodder was found to be crushed and broken up in excellent condition for feeding, due to the shearing effect and tremendous pressure of the plunger. This is thought to present a solution to the problem of utilizing corn fodder in cases where the corn crop is not large enough to justify the purchase of a shredder, and where there is not enough business to make custom shredding profitable. The machine used was a small hay press on trucks with a gasoline engine. The engine may be detached, put on other trucks, and used for belt and shaft work around the farm, making in all a handy device and profitable investment for the small farmer.

**The trials of potato diggers and potato sorters**, W. C. BROWN (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 243-252, figs. 5).—The results of trials of 7 potato diggers and 6 potato sorters are given and their strong and weak points noted. The decision of the judges favored a digging machine with 4 digger arms revolving behind the share to which are fitted 3 specially curved tines which dig and deposit the potatoes with a peculiar feathering action. This is a light machine built largely of wrought steel and malleable iron, and has a low draft and a silent and steady working motion which is helped by the 5:1 bevel gears running enclosed in an oil bath.

**The hydraulic ram**, W. C. DAVIDSON (*Breeder's Gaz.*, 61 (1912), No. 21, p. 1194, fig. 1).—Brief instructions are given for the installation and operation of a hydraulic ram.

**Making use of the siphon on the farm**, L. J. WRIGHT (*Wis. Country Mag.*, 6 (1912), No. 5, pp. 15, 16, fig. 1).—An outline of the method and requirements for using a siphon for conveying water from a well to a stock tank.

**Electric lighting plants for the farm** (*Farm Machinery*, 1912, No. 1082, pp. 16, 17).—A general discussion of the electric lighting systems most economical and efficient for the average large and small farm, outlining the method of computing the necessary lighting capacity of a plant and the methods of determining the apparatus necessary to supply the computed lighting energy. It is stated that for an average small farm \$250 will buy a 25-light plant, consisting of one 25-light, 40-volt dynamo, 1 switch board equipped with motors and switches, and one 16-cell, 120-ampere hour storage battery with fittings and electrolyte. This plant requires a 1½-horsepower or larger, steadily operating engine for good service.

**An investigation into the value of ferro or reenforced concrete for farm and estate purposes**, C. S. ORWIN (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 122-139, figs. 10).—A discussion of the use of reenforced concrete on the estates in England for the construction of farm buildings, farm laborers' cottages, and other farm equipment. The details of construction of several typical examples are given, including some original ideas as to reenforced column and wall construction for buildings, and demonstrating the ease and cheapness with which concrete work can be done on the farm by comparatively unskilled labor and 1 or 2 good foremen.

**The latest in circular barn construction**, H. C. CROUCH (*Ill. Agr.*, 16 (1912), No. 9, pp. 309-313, figs. 3).—The advantages of circular barns pointed out are convenience, strength, durability, and cheapness. The details of construction of a typical barn, which cost about \$2,000, are briefly presented.

**The construction of cow-byres,** W. S. H. CLEGHORNE (*Agr. Jour. Union So. Africa*, 3 (1912), No. 3, pp. 372-382, figs. 7).—The principles of the external and internal design and construction of single and double cow sheds are presented. The objects emphasized as to be kept in view are cleanliness, ventilation, lighting, comfort and health of cows, and economy of labor.

**An improved roof for the cow house,** R. HENDERSON (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 24 (1912), pp. 77-86, figs. 9).—The author points out the unsanitary features of the wooden or tile roof supported on a framework of wooden struts and rafters, and recommends and gives the details of construction of a nearly flat reenforced concrete roof supported by small steel girders. This construction presents a minimum resistance to air circulation and a minimum surface for the settling of dust and other unsanitary matter, and makes good ventilation and lighting possible.

**Ventilating the cow barn,** J. H. GRISDALE (*Canad. Thresherman and Farmer*, 17 (1912), Nos. 5, pp. 55-58, figs. 7; 6, pp. 53-57, figs. 8).—Some notes and observations are given on stable ventilation in general, with specific information as to the ventilation requirements of a given dairy stable and illustrated instructions for the installation of a suitable system.

**A modern granary,** J. E. BRIDGMAN (*Farm and Ranch*, 31 (1912), No. 23, p. 11, fig. 1).—Plans are given showing the construction of a granary and the location of equipment, the whole costing \$1,350.

**Cement stucco silo,** J. W. HART (*South. Agr.*, 42 (1912), No. 13, pp. 10, 11).—A bill of materials and the details of construction of a 12 ft. by 28 ft. cement stucco silo are given. This type of silo presents the qualities of strength, durability, cheapness, and neat appearance.

**Residential sewage disposal plants,** W. H. BOOKER (*Bul. N. C. Bd. Health*, 27 (1912), No. 4, pp. 146-156, figs. 7).—The author deals with the design, construction, and operation of small sewage disposal plants for isolated residences having not over 10 or 12 occupants, presenting the principles of purification by bacterial action in both the settling tank and filter bed or absorption area, and discussing surface sewage irrigation. He bases his design on an average daily flow of sewage per person of about 35 gal., and a size of septic tank to contain not over from 18 to 36 hours sewage flow for proper bacterial action.

## RURAL ECONOMICS.

**Monographs on agricultural cooperation in various countries** (*Internat. Inst. Agr. [Rome], Bur. Econ. and Soc. Intl., Monographs Agr. Co-oper.*, 1 (1911), pp. XVI+451).—This is a revised edition of a publication previously noted (*E. S. R.*, 24, p. 795). It presents notes and statistics on agricultural cooperation in various countries, including the following subjects: Historical and Statistical Sketch of the Present State of Agricultural Cooperation in Germany, Cooperative Land Credit Societies in Germany, and Present Conditions of Noncooperative Agricultural Associations; a General Sketch of Agricultural Organization in Belgium, Technical Work of the Professional Unions, Commercial Action of Professional Unions, Credit, and Cooperative Insurance; Cooperative Dairies, Cooperative Bacon Factories, Societies for Purchase and Sale, and Live Stock Improvement in Denmark; Historical Sketch of Agricultural Cooperation in British India, and The Cooperative Movement in 1908-9; Present State of Agricultural Unions in France, and Statistics Relative to Agricultural and Credit Cooperation; Noncooperative Agricultural Societies in the United Kingdom, Agricultural Cooperation in Great Britain and Ireland, Relations between the Agricultural Cooperative Movements in England, Scotland, and Ireland; Agricultural Cooperation and Associations in Norway, Holland, Russia, and Sweden.

Each of the monographs is preceded by demographic and economic statistics which serve as a general introduction to the study of each country.

**A cooperative dairy association**, W. M. REGAN (*Col. Farmer [Univ. Missouri]*, 9 (1912), No. 5, p. 17).—This article presents a concrete illustration in the Ozark Dairy Association near Springfield, Mo., of the possibilities of cooperation among farmers. When the association was started 5 years ago, the farmers were getting for their butter fat 6 cts. below the Elgin price, while last year the association sold for its 700 members \$320,000 worth of butter fat at an average of only 2 cts. below the Elgin price, and obtained 8 cts. per pound more last winter than nonmembers were receiving. This meant an increased profit of \$103 per member.

**Selling for more and buying for less**, J. ALVIN (*Country Gent.*, 77 (1912), No. 27, pp. 4, 5, 20, figs. 2).—This article describes in detail the organization and work of the Monmouth County Farmers' Exchange of New Jersey, which began operations in 1908 with a capital of \$7,000 and 350 members, by both buying and selling for its members. "In 1911 it did a business of \$1,499,500.99, saved its members over \$125,000, and made net profits of \$17,496.51." The capital stock for 1912 is reported at \$75,000, a surplus of \$25,000, and the membership at 1,100. The cost of administration is said to be 1½ per cent of the total business.

It is suggested that in such cooperative enterprises it is highly important that (1) farmers have sufficient products to permit of business on a considerable scale, (2) there should be some leading crop as the mainstay of the undertaking, and (3) the administration should be in the hands of men familiar with markets and marketing conditions. Much of the success of this enterprise is attributed to the charter requirement that all stockholders must ship through the exchange unless they receive at least 5 per cent more from outside competitors.

**Relation between the farmer and the railroad**, H. ELLIOTT (*Fargo, N. Dak.*, 1912, pp. 19).—An address at the Tri-State Grain and Stock Growers Association, Fargo, N. Dak., January 17, 1912, in which the speaker discusses the history and growth of agriculture, and emphasizes the importance of making farming more than ever a business, increasing production to meet the increasing population, and establishing a sentiment and demand for more scientific methods of farming. He points out the economic significance of the interrelation of farming and railroading and illustrates their interdependence.

**Government aid to small farmers**, R. FLEMING (*Daily Cons. and Trade Rpts. [U. S.]*, 15 (1912), No. 137, pp. 1044, 1045).—This report notes that the small landholders act of the Scottish Parliament, which became operative April 1 last, constituted a board of agriculture and a Scottish land court, each with distinct powers to facilitate the establishment of new agricultural holdings, and since April 1, more than 3,000 applications for registration as small landholders have been received. In case the landholders do not meet the demand by leasing small tracts to applicants on satisfactory terms, the board is authorized, upon payment of compensation for surface damage, etc., to provide by compulsory proceedings suitable land in each district sufficient to meet the demand of applicants. The board also has an annual grant not exceeding £200,000 to provide assistance to landholders, by way of a loan or gift as circumstances may warrant, for dividing, fencing, and draining lands, and erecting dwelling houses or other farm buildings.

**The small holdings movement** (*Economist*, 75 (1912), No. 3594, pp. 59, 60).—The progress of the small holdings movement in Great Britain since the passage of the 1908 act, is deemed fairly creditable, despite numerous complaints and criticisms.

Up to the end of 1911, 124,502 acres had been acquired for small holdings by county councils in England and Wales, of which 78,871 acres had been

purchased for £2,493,121. and 45,631 acres leased for rents amounting to £55,637. Of these, 94,154 acres had been let to 6,916 small holders, 186 acres sold to 13 small holders, and 4,597 acres let to 39 cooperative small holdings associations, which sublet the land to 732 of their members. Other applicants have been provided with land by private landowners, mainly through the instrumentality of the councils, making a total of 12,529 who have been provided with land.

Applications were received during 1911 from 4,301 individuals and 27 associations, of which 2,544 of the individuals and 16 associations have been provisionally approved for a total of 43,338 acres. During the 4 years since the act came into operation applications have been received from 35,187 individuals and 61 associations, for a total of 584,802 acres. Only 2.12 per cent of the applicants expressed a desire to purchase holdings.

**Agricultural credit and its benefit to the colonies, A. ZIMMERMANN** (*Rev. Econ. Internat.*, 9 (1912), II, No. 2, pp. 281-295).—This article discusses at length the problem of agricultural credit, the relation loans on mortgages, agricultural credit banks, and mutual cooperative organizations bear toward its solution, and how the systems as adopted by France, Germany, England, and Holland have affected the agriculture and the farmer in those countries.

**Rural credit banks** (*Rural World* [London], 24 (1912), No. 783, p. 128).—The author maintains that the establishment of these banks in England and Wales "has evidently not only added to the prosperity of many of the villagers, but has stimulated neighborly feeling by showing men how they can help their fellows by the exercise of care and mutual trust, without any real pecuniary risk to themselves, has encouraged thrift and efficient methods of cultivation, and has at the same time increased the self-respect of the individual members, and inspired them with hopes of progress."

**Seasonal distribution of labor on the farm, W. J. SPILLMAN** (*U. S. Dept. Agr. Yearbook 1911*, pp. 269-284, figs. 6).—This article presents a study as to the labor requirements of different crops and farm operations, looking to the formation of working plans that will secure a more economic use of the time of the farmer, his laborers, and his work stock. The possibility and expediency of planning cropping systems which will give regular employment to labor and thereby increase the area of land which a man or a definite number of men can farm are pointed out and emphasized, as well as some of the difficulties encountered. It is noted that when the farmer conducts some other industry in which the labor may well be intermittent, such as quarrying, mixing fertilizers, grinding agricultural lime, clearing land, cutting railroad ties, and the like, he may disregard the distribution of labor in planning a system of management, and devote his land only to those crops which are most profitable, but in doing this he must still take into account the cost of keeping idle horses and must plan a system of soil management that takes account of the future productivity of his land.

Charts are given illustrating the distribution of man and horse labor for each month of the year on field crops on a New England dairy farm, a New York potato and bean farm, a Dakota grain farm, and a general farm in the Middle West. A detailed work schedule of field labor on 240 acres of crops consisting of corn, wheat, hay, and an estimated seasonal requirement and distribution of labor necessary to produce 80 acres each of corn, of wheat, and of timothy and clover hay in a 6-year rotation in the latitude of central Missouri are also presented.

**Agricultural opportunities** (*U. S. Dept. Com. and Labor, Bur. Immigr. and Nat. Agr. Opportunities, 1912, Nos. 1, pp. 32; 2, pp. 36; 3, pp. 23; 4, pp. 32; 5, pp. 36; [6], pp. 32; [7], pp. 32*).—These publications present information concerning physical characteristics, resources, and products of the various States of the

United States, together with Alaska and Hawaii, special attention being given to principal crops grown, prices of farms, climate and soil, stock raising, etc.

[A tour through the cotton belt of the U. S. A., 1911]. G. S. HENDERSON (*Agr. Jour. India*, 7 (1912), No. 2, pp. 175-190, pls. 10).—This article presents notes gathered on a tour through the cotton belt of the United States in 1911, showing that the yield of cotton for the last 10 years has varied from 9,500,000 bales to over 13,000,000 bales, and the price per pound of lint from 8 cts. to over 14 cts., while the price of Egyptian cotton has fluctuated between 3.8 and 5.3 cts. Observations are also made as to the types of soil and cultural methods in different States, significance of insect pests and diseases of cotton, the use of farm machinery, the tendency after the civil war for the large plantations to be broken up and cultivated by small landowners or tenants, systems of tenancy, and the tendency of corporations or syndicates to purchase and operate very large areas.

Cotton production, 1911 (*Bur. of the Census [U. S.] Bul. 114, pp. 61, figs. 14*).—A census report presented under the following heads: "(1) Annual cotton production in the United States, as returned by ginner and delinters, distributed by States and counties, from 1907 to 1911, inclusive, with statistics of production for previous years; (2) world's cotton production from 1907 to 1911, by countries; and (3) supply and distribution of cotton in the United States for specified periods, 1909 to 1912, inclusive."

The quantity reported for the year with linters included and round bales counted as half bales was 16,109,349 running bales, the largest crop ever produced, 5,934,894 bales more than in 1909, and 2,570,322 bales more than in 1904.

[Live stock on farms and elsewhere in the United States] (*Bur. of the Census [U. S.] Bul. 13, pp. 34, figs. 6*).—This bulletin presents the principal results of the enumeration of live stock in the United States by the last census, including the totals both by geographic divisions and by States, and summarized as follows:

*Number of domestic animals on farms and elsewhere in the United States in 1910 and 1900, their value in 1910, and other data.*

	All domestic animals.	All cattle.	Dairy cows.	Horses, mules, asses, and burros.	Swine.	Sheep.	Goats.
Number in 1910:							
On farms.....		61,803,866	20,625,432	24,148,580	58,185,676	52,447,861	2,915,125
Not on farms.....		1,878,782	1,170,338	3,469,662	1,287,960	390,887	114,670
Number in 1900:							
On farms.....		67,719,410	17,135,633	21,625,800	62,868,041	61,503,713	1,870,599
Not on farms.....		1,616,422	973,033	3,126,636	1,818,114	231,301	78,353
Value in 1910:							
On farms.....	\$4,760,060,093	\$1,499,523,607	\$706,236,307	\$2,622,180,170	\$399,338,308	\$232,841,585	\$6,176,423
Not on farms.....	\$536,361,526	\$60,816,261	\$47,001,623	\$463,280,313	\$10,076,260	\$1,822,943	\$365,749
Average value per head, 1910:							
Total.....		\$24.50	\$34.56	\$111.72	\$6.88	\$4.44	\$2.16
On farms.....		\$24.26	\$34.24	\$108.59	\$6.86	\$4.44	\$2.12
Not on farms.....		\$32.37	\$40.16	\$133.52	\$7.82	\$4.66	\$3.19
Farms and inclosures reporting:							
Farms.....	6,034,783	5,284,916	5,140,869	.....	4,351,751	610,894	82,755

Final report on grain crops and live stock of the Province of Saskatchewan (*Saskatchewan Dept. Agr. Bul. 29, 1912, pp. 30, pl. 1*).—As compiled from returns by individual farmers and the department's regular staff of crop correspondents, the total production for the year 1911 of wheat, oats, barley, and flax was 212,710,363 bu. or 67,825,513 bu. over the previous year. This was grown on 8,602,455 acres, an increase of 1,220,390 acres over 1910.

The number of live stock in the Province was as follows: Horses 574,972, milch cows 231,297, other cattle 546,205, sheep 125,072, swine 333,218, and poultry 4,643,858, all being largely increased over 1901.

Report of the department of agriculture and immigration for the year ending December 31, 1911 (*Rpt. Dept. Agr. and Immigr. [Manitoba], 1911, pp. 113*).—The considerable increase in the output of agricultural products in Manitoba for 1911 over previous years is shown in the following table:

*Acres and yield per acre of crops in Manitoba for a period of years.*

Crops.	Acres.					Yield per acre.				
	1890	1895	1900	1905	1911	1890	1895	1900	1905	1911
Wheat.....	<i>Acres.</i> 746,058	<i>Acres.</i> 1,140,276	<i>Acres.</i> 1,457,396	<i>Acres.</i> 2,643,588	<i>Acres.</i> 3,339,072	<i>Bu.</i> 19.65	<i>Bu.</i> 27.86	<i>Bu.</i> 8.9	<i>Bu.</i> 21.07	<i>Bu.</i> 18.29
Oats.....	235,534	482,658	429,108	1,031,239	1,628,562	40.2	48.73	20.5	42.6	45.3
Barley.....	66,035	153,839	155,111	432,298	759,977	31.33	36.69	18.9	34.2	31.5
Flax.....		82,668	20,437	24,707	85,836		15.5	8.04	13.02	14.0
Potatoes.....			16,880	25,835	44,478			132.0	187.0	187.0

Poultry disposed of by farmers during the year numbered 941,776; farm buildings constructed were valued at \$3,273,487; butter marketed by farmers amounted to 4,547,827 lbs. at an average of 21.4 cts. per pound; and live stock in the Provinces numbered 251,572 horses, 407,611 cattle, 37,227 sheep, and 192,386 pigs.

Agricultural statistics, 1911 (*Bd. Agr. and Fisheries [London], Agr. Statis., 46 (1911), No. 3, pp. 188-274, fig. 1*).—This report shows by notes and tables the prices and quantity of wheat, corn, barley, oats, live stock, and other agricultural produce in Great Britain in 1911.

[Agricultural review of Hungary], P. NASH (*Daily Cons. and Trade Rpts. [U. S.], 15 (1912), No. 152, pp. 1381-1391*).—The grain crop of 1911 is reported at 576,639,000 bu., some 3,000,000 bu. less than in the preceding year. Decreases are also noted in the potato, sugar beet, and tobacco crops. The production of wine was 105,668,000 gal. as compared with 60,750,000 gal. in 1910. The number of cattle is increasing, but not sufficiently to meet the demand, and imports of meat and butter are necessary.

The formation is noted of the National Union of Hungarian mortgage banks, planned to assist small farmers by buying large estates, dividing them into small parcels, and selling them on extremely easy terms. The bank also loans money to farmers for investment on their farms to be repaid in small annual sums for periods ranging from 20 to 40 years. The bank is capitalized at \$3,045,000, of which the government furnishes \$1,624,000.

Roumanian agricultural statistics, J. B. JACKSON (*Daily Cons. and Trade Rpts. [U. S.], 15 (1912), No. 138, p. 1084*).—Data are reported for the principal crops. "Roumania's agricultural production in 1911 had a total value of \$269,042,000, which was \$17,273,500 more than in 1910. Cereals made up about 83 per cent of the total."

[**Production statistics in Australia**], G. H. KNIBBS (*Commonwealth Bur. Census and Statis. Melbourne Prod. Bul. 5, 1912, pp. 9-48*).—This bulletin presents notes and tables dealing with production statistics of Australia and contains particulars relative to land settlement; number and area of private holdings; acreage, yield, and value of each of the principal crops in the several States for a period of years; value of implements and machinery employed in agriculture, dairying, and pastoral holdings; quantity and value of agricultural products imported and exported, 1901-1910 inclusive; number of live stock, estimated production, and value; and quantity and value of principal farmyard and dairy products, bee and poultry products, etc.

**Prerequisites for the agricultural development of Ugogo in German East Africa**, P. VAGELER (*Tropenpflanzer, Beihefte, 13 (1912), No. 1-2, pp. VII+127, pl. 1, figs. 18*).—This is an account of studies of the topographical, climatic, hydrographic, soil, and agricultural conditions of Ugogo, a small district near the central part of German East Africa.

The soils of the region naturally group themselves into red and gray types, the latter covering about 94 per cent of the area. The residual red soils occupy the more broken ridges, and the alluvial formations the small stream bottoms. The red soils are said to be rich in lime, potash, and humus, but poor in phosphoric acid and nitrogen. The residual gray soils occupy the higher level hill-tops and the plateaus. The alluvial gray soil is found in the swampy regions. The gray soils of the plateaus constitute the most widely distributed type. They are poor in plant food constituents. The gray alluvial is much more fertile than the residual type.

Grain and live stock production constitute the principal agricultural industries. The author believes that this region offers opportunities for colonial development, and recommends the utilization of underground waters, a thorough study of the climatic conditions, the establishment of an agricultural experiment station, and the breeding of animals adapted to the climatic conditions.

## AGRICULTURAL EDUCATION.

**Agricultural college and economic aspects of farming**, J. W. PINCUS ([*Amerherst, Mass., 1912*], pp. 4).—In this address, delivered before the students of the Massachusetts Agricultural College, May 20, 1912, the author points out the importance to the farmer of the problems of cooperation, improvement of agricultural credit, and social life, and suggests how the agricultural college and its graduates may become potent factors in the rejuvenation of country life.

**The commercial side of farm education**, A. M. LOOMIS (*Tribune Farmer [N. Y.], 11 (1912), No. 546, p. 18*).—It is brought out in this article that the lack of money to carry out and put into practice the ideas and methods advocated at agricultural schools and colleges for increasing the fertility of the farm and growing better crops emphasizes the need of special instruction for financing and marketing crops. It is necessary to teach the farmer how to increase the yield of his land, but it is equally important for him to know how to make his farm products yield the greatest possible profits.

**Education for the Iowa farm boy**, H. C. WALLACE (*Des Moines, Iowa, [1911], pp. 28*).—In this paper, read before the Prairie Club of Des Moines on December 17, 1910, the author outlines the agricultural conditions leading to the need for better farming and larger crops, and in consequence the importance to the Nation of the education of the farmer. The paper considers what has been and is now being done to educate the future farmers; compares general methods of education followed in Germany, France, and England with those followed in America; deals with secondary agricultural education in foreign countries and the United States; and reviews agricultural education conditions in Iowa.

Some needs in forestry education, H. P. BAKER (*Forestry Quart.*, 10 (1912), No. 1, pp. 45-49).—This is a discussion as to whether our courses in forestry should be strengthened along lines of natural science or engineering.

"The fact that all men from either 4 or 6 year courses have been placed upon nearly the same basis upon entering practical work has produced an attitude, a condition . . . which must be changed somewhat before the problem of filling the gap between the practically untrained guard and ranger of today and the technical assistant is solved." A solution suggested at the recent conference of forest schools in Washington "is the establishment of a series of well-equipped ranger schools giving from 2 to 3 years of intensely practical work and fitting men for work in specific regions rather than for the entire country." Or it might be agreed "that the function of the undergraduate forest school is a training especially strong in civil and mechanical engineering, that the graduates may fit immediately into such work as reconnoissance surveying as practiced in the National Forests, or estimating and surveying as now carried out in the Appalachians, or the planning and carrying out of logging operations; . . . that a man so trained and with a bachelor's degree only should not be called a forester until he had taken 1 or 2 years of advanced work in technical forestry, after a year or two of experience."

In public high schools should agriculture be taught as agriculture or as applied science? W. R. HART (*Yearbook Nat. Soc. Study Ed.*, 11 (1912), pt. 2, pp. 91-97).—The author assumes that agriculture may be taught in either of these ways, but concludes that because of time limitations and desirability of maintaining human interest, the former is to be preferred.

In the public high schools agriculture should be taught as agriculture, not as applied science, G. F. WARREN (*Yearbook Nat. Soc. Study Ed.*, 11 (1912), pt. 2, pp. 98-101).—The author emphasizes the fact that agriculture is too new and rapidly growing a science to be best taught by having the principles presented in the separate sciences. To keep all the science text-books emphasizing agriculture up to date would be an impossible task, and further, "our text-books of science are not written by persons who know much about agriculture." The sciences are also of world-wide application, whereas certain phases of agriculture are essentially local in their pedagogy. Another reason advanced is that "our teachers of science are not likely ever to know enough about agriculture to be able to go very far with the introduction of agriculture into the sciences."

The author holds that agriculture is an independent science in itself, as independent, for example, as medicine, where "we should not think of expecting the teachers of botany, zoology, chemistry, and physics to train physicians." Illustrations are given to show that trying "to give agricultural training without agriculture as a separate subject is like Hamlet with Hamlet left out."

Potentiality of the school garden, C. A. STEBBINS (*Addresses and Proc. Nat. Ed. Assoc.*, 49 (1911), pp. 1131-1137).—An address delivered before the National Education Association at San Francisco, in which the author points out the possibility of the school garden to give new direction to old subjects and create a sentiment for farming, for country life, and to link together school life and community life generally. This is done, as he suggests, by making the garden what might be called an embryo community, where children may be brought naturally in contact with those factors which they are to meet later in life. Here the child may have demonstrated to him, through primitive methods of farming, marketing, banking, etc., the civic evolution of his race, and at the same time be brought in contact with the activities of the world; for example, flax may be grown, later the fiber may be separated and used in weaving; from this may be brought out lessons as to the world's work in clothing its people.

It is stated that the school garden further offers opportunities for forming a correct social personality early in life. "Early in their garden life the children learn to respect those things that belong to their neighbors; to realize that community property belongs to the whole, not to a part, but that each must offer his support; to understand that the policy which is the best for the majority must be supported . . . to feel, in general, that each represents but one small part of a great whole and that each must do his best to fit in smoothly."

**City congestion and farm desolation, J. KRAUSKOPF** (*[Doylestown, Pa.: Nat. Farm School, 1911], pp. 20, figs. 2*).—In this address the Ghetto conditions in New York City are described and the need of more institutions like the National Farm School at Doylestown, Pa., to help prepare immigrants for life on the farm is emphasized.

**Popular farm education in Canada, A. FULLERTON** (*Country Gent., 77 (1912), No. 22, pp. 3, 31, figs. 3*).—The author describes some of the work of the Ontario Agricultural College, particularly those features relating to the education of adult farmers, including excursions to the college, short courses, and the appointment of graduates of the college as farm advisers. In 1911, 20 counties were supplied with farm advisers.

**Agricultural education in Trinidad—past, present, and future, A. FREDHOLM** (*Proc. Agr. Soc. Trinidad and Tobago, 12 (1912), No. 4, pp. 96-103*).—An account is given of the development of agricultural instruction in Trinidad. Instruction in agriculture is included in the curriculum of the public schools, with school gardens for practical demonstrations, and a system of apprenticeships.

**Eleventh annual general report of the Department of Agricultural and Technical Instruction for Ireland** (*Dept. Agr. and Tech. Instr., Ireland, Ann. Gen. Rpt., 11 (1910-11), pp. VI+518*).—This is a report on the department's administration and funds and on the details of its work during 1910-11, including agricultural and technical instruction, and presents data corresponding to the report for the previous year (E. S. R., 25, p. 494).

**Itinerant schools of agriculture for young women (home economics) and for young men, J. M. GUILLON** (*Bul. Mens. Off. Renseign. Agr. [Paris], 10 (1911), No. 6, pp. 711-736*).—The author discusses in detail the origin, aim, organization, instruction, and budget of these schools.

**Agricultural schools, U. BRANDER** (*Fennia: Bul. Soc. Geogr. Finlande, 30 (1910), pt. 2, Carte 33, pp. 14-25*).—This is a historical review of the establishment of agricultural schools in Finland. It shows that in 1910 the following 129 institutions received government aid for agricultural instruction: A section of agriculture at the University of Helsingfors; an agricultural institute at Mustiala; an agricultural high school at Kronoborg; an agricultural lyceum at Helsingfors; 9 agricultural schools with 2-year courses, 1 with a 1½-year course, and 1 with a 1-year course; 2 farm schools with 2 winter courses, and 16 with 1 winter course; 6 itinerant farm schools extending through 2 months; 12 public high schools offering agricultural instruction; 5 gardening schools; 10 horticultural and home economics schools; 8 home economics schools; 4 theoretical animal husbandry schools; 4 animal husbandry and dairy schools; 3 2-year, 31 1-year and 1 itinerant animal husbandry schools, 3 theoretical dairy schools; 1 1-year dairy school; 2 schools for grooms; 5 farriery schools; and 1 school of apiculture. A brief bibliography is appended.

**Agricultural education [in Victoria], A. M. LAUGHTON** (*Victorian Yearbook, 31 (1910-11), pp. 623-639*).—A brief summary of the work and progress of each of the agricultural colleges, schools, and experiment stations in Victoria is here presented.

**Elements of agriculture**, W. FREAM (*London, 1911, 8. ed., pp. XIII+692, pls. 18, figs. 270*).—This text-book, prepared by authority of the Royal Agricultural Society of England, was edited and revised in the eighth edition by J. R. Ainsworth-Davis. It consists of 3 parts: (1) The soil, including chapters on formation, composition and classification, physical properties, sources of loss and gain, improvement and tillage of soils, agricultural implements, and manures and manuring; (2) the plant, including chapters on seeds and their germination, structure and functions of plants, cultivated plants, weeds, selection of seeds, grass land and its management, farm crops, hardy fruit culture, and fungus pests; (3) the animal, including chapters on structure and functions of farm animals, composition of the animal body, foods and feeding, principles of breeding, breeding, feeding, and management of horses, cattle, sheep, and pigs, fattening of cattle, sheep, and pigs, dairying, poultry and poultry keeping, and harmful and beneficial animals.

**Some suggestions regarding rural school agriculture**, L. R. WALDRON (*Dakota Farmer, 32 (1912), No. 10, pp. 540, 541*).—The author suggests simple experiments in plant breeding, soils and soil physics, farm crops, plant diseases, germination of seeds, and a study of the weather, for use in public schools.

**Corn**, C. A. McMURRY (*El. School Teacher, 12 (1912), No. 7, pp. 297-305*).—In this, the first of 3 papers which constitute the report of a committee of the Superintendents' and Principals' Association of Northern Illinois, the subject of corn is treated as a geography topic for the fifth or sixth grade. The paper presupposes lessons on corn in the earlier grades and suggests a historical consideration of the subject, the problem of corn production on a large scale in the corn belt, and a comprehensive survey of its importance in the world.

**School exercises with corn**, T. I. MAIRS (*Penn. State Col. Bul., 6 (1912), No. 2, pp. 20, figs. 7*).—This bulletin, which is intended for teachers rather than pupils, consists of 3 parts, suited, respectively, to the fall, winter, and spring and summer. The exercises embrace some that are suitable for all grades from the fifth or sixth to the upper classes of the high school.

**Arbor Day manual** ([*Boise*], *Idaho: Dept. Pub. Instr., 1912, pp. 24, figs. 2*).—The history of Arbor Day, directions for improving the school ground, including the preparation of a planting plan, selecting and obtaining trees and how to plant them, list of decorative trees and shrubs native to Idaho, and questions and answers for the instruction of pupils in the protection of forests are given.

**Arbor Day annual, 1912**, compiled by G. M. WILEY (*Albany, N. Y.: Ed. Dept., 1912, pp. 70, pls. 4, figs. 42*).—This annual is devoted to fruit trees in New York and includes the following articles: Arbor Day and Our Fruit Trees, by A. S. Draper; The Fruit Tree, by L. H. Bailey; Fruit Production in New York, by C. J. Huson; Orchard Management, by U. P. Hedrick; Cross Pollination of the Pear and Apple, by H. M. Dunlap; and The Care of Fruit Trees, by B. J. Case. These are followed by a short list of varieties of fruit for the home orchard and garden, and a suggested program and poems for Arbor Day.

**Forest primers**, D. E. BURCEZ, D. J. LAPIE, and G. LAPIE (*Cartilla Forestal. Mexico: Sec. Fomento, 1909, No. 1, pp. 35; 1910, No. 2, pp. 62; 1911, No. 3, pp. 57*).—These primers, which have been prepared by the professors of the schools for forest guards and revised and amplified by the central board of forestry, are résumés of the instruction given to students who wish to become forest guards. The first primer gives instruction concerning forest nurseries, the second on silviculture, and the third on reforestation.

**A study of food, II**, edited by MARY P. VAN ZILE (*Agr. Ed. [Kans. Agr. Col.], 3 (1910), No. 9, pp. 58, figs. 7*).—This concludes a previous article (E. S. R., 26, p. 493).

Some results of the farmers' cooperative demonstration work, B. KNAPP (*U. S. Dept. Agr. Yearbook 1911*, pp. 285-296).—This paper takes up in detail the purposes, scope, and success of the farmers' cooperative demonstration work in the Southern States.

### MISCELLANEOUS.

**Yearbook of the Department of Agriculture, 1911** (*U. S. Dept. Agr. Yearbook 1911*, pp. 732, pls. 67, figs. 20).—This contains the report of the Secretary on the work of the Department during the year; an account by B. T. Galloway of the life and work of the late Dr. S. A. Knapp (pp. 151-154); 30 special articles abstracted elsewhere in this issue; and an appendix containing an article by J. A. Arnold on the Publications of the United States Department of Agriculture and How They are Distributed; Review of Weather Conditions during the Year 1911, by P. C. Day; a directory of the Department, the agricultural colleges, the experiment stations, and state officials in charge of agriculture; and agricultural statistics, including summary tables from the agricultural returns of the thirteenth census as to number, area, and value of farms; value of farm buildings and live stock; farm expenses; mortgages; and nativity of families.

**Twenty-fourth Annual Report of Alabama College Station, 1911** (*Alabama Col. Sta. Rpt. 1911*, pp. 43).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1911, and reports of the director and heads of departments on the work of the station during the year. A portion of the report of the entomologist is abstracted on page 554 of this issue.

**Twenty-second Annual Report of Arizona Station, 1911** (*Arizona Sta. Rpt. 1911*, pp. 515-572, pl. 1, figs. 2).—This contains the organization list, an administrative report by the director on the work and publications of the station, a financial statement for the fiscal year ended June 30, 1911, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue.

**Twenty-fourth Annual Report of Vermont Station, 1911** (*Vermont Sta. Rpt. 1911*, pp. XXVII+444+28, pls. 18, figs. 50).—This contains the organization list, a brief announcement concerning the station, a financial statement for the fiscal year ended June 30, 1911, a report of the director on the publications and work of the station, and reprints of Bulletins 155 to 160, and Circulars 6 to 8, previously noted.

**Index to publications of the Hawaii Agricultural Experiment Station, July 1, 1901, to December 31, 1911**, A. T. LONGLEY (*Hawaii Sta. [Spec. Pub.]*, 1912, May 24, pp. 38).

**Monthly Bulletin of the Department Library, April, May, and June, 1912** (*U. S. Dept. Agr., Library Mo. Bul.*, 3 (1912). Nos. 4, pp. 113-142; 5, pp. 145-178; 6, pp. 181-206).—These numbers contain data for April, May, and June, 1912, respectively, as to the accessions to the Library of this Department and the additions to the list of periodicals currently received.

**Experiment Station Work, LXIX** (*U. S. Dept. Agr., Farmers' Bul.* 499, pp. 24, figs. 5).—This number contains articles on the following subjects: Top-dressing pastures, making hay, a fresh-air brooder, roosting closet for poultry, exhibition contests for improving dairy products, blind staggers of horses, adobe as a building material, and white and color washes.

## NOTES.

---

**Iowa College and Station.**—A recent decision of the state board of education relative to the coordination of the instruction in higher education makes radical changes in the scope of the existing state institutions. Under the new plan all work in engineering will be concentrated at the College of Agriculture and Mechanic Arts; the courses in professional education and the literary arts at the State Teachers College extending beyond the sophomore year will be discontinued and centered at the State University; and all courses in general science and domestic science at the College of Agriculture and Mechanics Arts will be discontinued and a school of household arts established at the State University. It is proposed to put the new plan into effect at the end of the present college year.

L. A. Maynard, assistant in chemistry, and H. C. Cosgriff, field superintendent, have resigned, and will be succeeded respectively by J. C. Reese and C. R. Forest.

**Kansas Station.**—Director E. H. Webster has resigned to become associate editor of *Hoard's Dairyman*, January 1, 1913.

**Kentucky University and Station.**—The establishment of a series of about 12 demonstration farms of about 20 acres each has been authorized, and arrangements whereby four of these farms, all located in the western part of the State, will be donated to the station have been practically completed.

Dr. J. H. Kastle has been appointed dean of the college of agriculture and director of the station. Frank T. McFarland, a 1912 graduate of the Ohio State University, has been appointed instructor in botany.

**Louisiana Stations.**—R. G. Fuller and Rene Baus have resigned as assistant chemists in the field and fertilizer laboratory.

**Mississippi Station.**—B. W. Auspon, assistant horticulturist, has become professor of floriculture and landscape gardening at the Maryland College.

**Cornell University.**—John W. Spencer, widely known as the organizer of the farmers' reading courses, the nature study courses for children, the junior naturalists' clubs, and the junior gardeners' clubs, died at Ithaca October 24, at the age of 69 years.

**Pennsylvania College and Station.**—Alva Agee has resigned as professor of agricultural extension and secretary of the school of agriculture to become, on December 1, head of the extension service of the New Jersey College and Stations. C. F. Shaw has resigned as assistant professor of agronomy and agronomist to become soil technologist in the University of California. John W. Gregg has resigned as assistant professor of horticulture and assistant horticulturist to become professor of landscape engineering in the University of California, beginning January 1, 1913.

**Rhode Island Station.**—Dr. H. J. Wheeler, whose resignation as director has been previously noted, has been appointed to the newly established position of agricultural-chemical expert of the American Agricultural Chemical Company, beginning December 1.

**Virginia Truck Station.**—F. E. Miller, a recent graduate of the University of Missouri, has accepted the position of assistant horticulturist. J. E. Pickett has been appointed horticultural foreman.

# EXPERIMENT STATION RECORD.

## CONTENTS OF VOL. XXVII, NO. 7.

Editorial notes:	Page.
The anniversary of agricultural education.....	601
The influence of the land-grant colleges on higher education.....	605
Recent work in agricultural science.....	609
Notes.....	696

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Technical methods of chemical analysis, trans. and edited by Keane et al.....	609
Solubility determinations in agricultural chemistry, Rindell.....	609
A modification of the diphenylamin test, Withers and Ray.....	609
Determination of lithium, Skinner and Collins.....	609
A method of estimating calcium carbonate in soils, Shrewsbury.....	610
The estimation of ammonia in carbonated waters, Elsdon and Evers.....	610
Nitric nitrogen in mixed fertilizers, Peck.....	610
Report of the committee on phosphate rock, Richardson et al.....	610
The forms of phosphorus in cotton-seed meal, Rather.....	611
Lutein obtained from egg yolks, Willstätter and Escher.....	611
Soy-bean oil, Matthes and Dahle.....	611
Valuation of tea, Besson.....	612
The synthetic properties of antiemulsin, Bayliss.....	612
Determination of crude fiber in finely powdered materials, Greifenhagen.....	612
In regard to the determination of lecithin, Salzman.....	612
Flocculation of lecithin and lecithin protein mixtures with acids, Feinschmidt..	612

	Page.
Estimation of minute amounts of arsenic in foods, Clark and Woodman.....	613
Honey and its analysis, Muttelet.....	613
Examination of marmalades and milk chocolates, Härtel.....	613
Cider vinegar, Mott.....	613
The detection of benzoic acid in coffee extract, Lythgoe and Marsh.....	613
Spirit of nitrous ether, Hanson and Burke.....	614
Use of saponin for homogenizing samples of milk to be examined, Frouin.....	614
A new method for determining fat and salt in butter, Shaw.....	614
The index of refraction of the mixed acids of fatty oils, Smith.....	614
Coconut fat with a high iodine number, Vaubel.....	615
Abnormal beeswax, Buchner.....	615
Separation of phosphorus compounds of feedstuffs, Fingerling and Hecking....	615
The determination of moisture content of beet seeds, Plahn.....	615
A chemical-technical vade mecum for sugar refineries, Gröger.....	615
The carbohydrate constituents of Para rubber, Pickles and Whitfield.....	615
Helianthus tubers for alcohol production, von Hérics-Tóth and von Osztróvsky	616
Progress of chemistry for 1911, edited by Cain and Greenaway.....	616
Proceedings of Official Agricultural Chemists, edited by Wiley and Pierce....	616

## METEOROLOGY—WATER.

Monthly Weather Review.....	616
Meteorological observations at Massachusetts Station, Ostrander and Angier....	617
Report of director of the [Philippine] Weather Bureau for 1908, Algué.....	617
Influence of climatic conditions on agricultural industry of Germany, Schnider.	617
The consideration of snow, Church, jr.....	617
Drinking-water supply of primitive people, Haberlandt.....	617

## SOILS—FERTILIZERS.

Soils of the eastern United States and their use, XXXVIII-XI, Bonsteel.....	617
The soils of Tripoli, Vinassa de Regny.....	618
Researches on properties of peat soils of Picardy, Coquidé.....	619
Black soils (chernozem), Kossovich.....	619
Gray sand and ortstein, Niklas.....	619
The chemical composition of red saline clay, Marcus and Biltz.....	619
A peculiarity of the mole, Gmelin.....	619
The cause of the absorbent power of soils, Pratalongo.....	619
A method of retaining water in the soil, Krebs.....	619
The cooperation of organisms in clay formation, Rohland.....	619
The flocculating power of some soluble salts on clay, Masoni.....	620
Biochemical studies on soils subjected to dry heat, Seaver and Clark.....	620
Bacterial slimes in soil, Greig-Smith.....	620
The determination of Rhizobia in the soil, Greig-Smith.....	620
The rôle of Streptothrix in the soil, Fousek.....	620
The agricere and the bacteriotoxins of the soil, Greig-Smith.....	621
Beneficial effect of creatinin and creatin on growth, Skinner.....	621
Partial sterilization of soil, McBride.....	621
Partial sterilization of soil for greenhouses, Russell and Petherbridge.....	621
Clearing heavy lands as adapted to Montaja and Panendjoan, Van Lennep.....	621
Reclamation of crawfish lands, Garrison.....	621
Sponge spicules in swamp soils, Davis.....	622
Sponge spicules in certain soils, Davis.....	622
Present status of fertilizer investigations, Cameron.....	622
Some secondary actions of manures upon the soil, Hall.....	622
A biological method of preserving manure, Barthel and Rhodin.....	623
Relations between ash constituents of various fertilized plants, Leoncini.....	623
Utilization of atmospheric nitrogen, Norton.....	623
The fixation of atmospheric nitrogen by the use of aluminum nitrid, Marre....	624
Behavior of calcium cyanamid under influence of soils and colloids, Henschel.	624
Further investigations on lime nitrogen, Milo.....	625
Lime nitrogen as regards its transformation in the soil, Milo.....	625
New observations on the behavior of nitrate in cultivated soil, Vogel.....	626
Influence of organic substances on nitrogenous compounds, Gerlach and Densch	626
The action of lime nitrogen and calcium nitrate in the field, Gerlach.....	626
The phosphate deposits of the United States, Waggaman.....	627
Composition of Palestine phosphates and their fluorine content, Danelli.....	627
The utilization of the phosphates of central Russia.....	627

	Page.
[Experiments with different phosphates], Prianishnikov et al.....	627
Field investigations for potash in America, Gale.....	627
Alunite as a source of potash, Waggaman.....	628
The extraction of potash from silicate rocks, Ross.....	628
Action of magnesium [and manganese] fertilizers and boric acid, Andouard....	628
Studies on catalytic fertilizers, Boullanger.....	628
The stimulating action of manganese, Quante.....	629
Study of sulphur as a fertilizer, Giannetto.....	629
Utilizing sludge in Bradford, England.....	629
City street sweepings as a fertilizer, Skinner and Beattie.....	629
Review of progress in the fertilizer industry, 1909-1911, Wichern.....	629
[Fertilizers].....	629

## AGRICULTURAL BOTANY.

Alterations in the velocity of growth of certain seedlings, Congdon.....	630
Dry matter, nitrogen, and mineral content of trees, Ramann and Bauer.....	630
The mineral content of tree foliage as affected by day and night, Ramann.....	630
Changes in the osmotic pressure of the sap of the leaves, Dixon and Atkins....	631
Formation of mechanical tissue as influenced by tension and contact, Brush...	631
The admission of anilin colors into living plant cells, Küster.....	632
Respiration pigments in oxidation processes of plants, Palladin.....	632
Distribution of pigment in the seed coat of the cowpea, Mann.....	632
The distribution of oxidases in plants and their rôle, Keeble and Armstrong...	632
The occurrence of urease in higher plants, Zemplén.....	633
The action of bisulphid of carbon on the germination of seeds, Finzi.....	633
Nutritive changes in sprouting pumpkin seeds, Periturin.....	633
The formation of asparagin in sprouting vetches, Ritman.....	634
Protein formation by sterile cultures of higher plants in darkness, Shulov.....	634
The utilization of ammoniacal nitrogen by corn plantlets, Kalinkin.....	634
Utilization of ammonium salts by green plants, Pantanelli and Severini.....	634
The presence of nitrifying bacteria in ordinary sand cultures, Shulov.....	634
On the presence of glutamic acid in the tomato, Monti.....	634
On anthocyanin-forming bodies, Politis.....	634
On the presence of free hydrocyanic acid in plants: II, Ravenna and Babini..	635
The selective power of plants for dextrose and levulose, Lindet.....	635
Potassium in relation to carbohydrate formation and decomposition, Stoklasa..	635
The action of sulphurous acid on pollen, Sabachnikoff.....	635
Injury to plants by vapors and dust from tarred roads, Gatin.....	635
Influence of starvation of the ascendants upon the descendants: I, Harris.....	636
Chromosome numbers in Triticum and Egilops, Bally.....	636
Soil moisture in the cottonwood dune association of Lake Michigan, Fuller....	636
Rates of evaporation in certain associations in Illinois, Gleason and Gates....	636
Seeds and plants imported from July 1 to September 30, 1911.....	637

## FIELD CROPS.

Results obtained in 1911 on the Dominion experimental farms, Saunders.....	637
Report on experiments, botanical station, Salisbury, 1910-11, Hampton.....	637
Report of experimental work of the Bankipore Agricultural Station, 1910-11...	637
Annual report of the Cuttack Experimental Farm, 1910-11, Dobbs.....	637
Annual report of the agricultural stations in eastern Bengal and Assam, 1911..	638
Report of demonstration farm, Kalimpong, for the year 1910-11, Goodwin.....	638
Field crops at the Taganrog Experiment Field during 1899-1908, Olenin.....	638
Moor culture handbook, Bersch.....	638
Manuring of meadow land.....	638
Manuring of poor hill pastures.....	638
The grain crops, Hoffmann.....	638
Rate of sowing summer cereals, Danilenko.....	638
Grain sowing in wide rows, Danilenko.....	639
The composition of Cape barley, Juritz.....	639
The dissemination of brewing barley in Germany, Schulze.....	639
Bogoroditsch Experiment Field, Pulman.....	639
The manuring of carrots, Stokes.....	639
Manurial experiments on maize, Vipond.....	639
Corn growing in the East, Hunt.....	639
How to grow 100 bushels of corn per acre on worn soils, Smith.....	640

	Page.
Observations on certain extra Indian Asiatic cottons, Leake and Pershad.....	640
The branching habits of Egyptian cotton, McLachlan.....	640
Cotton improvement under weevil conditions, Cook.....	640
The influence of Russian weather conditions in 1902 on oats, Mikhallovskii....	641
Wild oats and false wild oats: Nature and distinctive characters, Criddle.....	641
Report of Dumraon Agricultural Experiment Station, 1910-11, Dobbs.....	641
The "Ráb" system of rice cultivation in western India, Mann et al.....	641
Mutual relations of weight and sugar content in sugar beets, Andriik et al.....	642
Relationship of weight and sugar content of beets, Andriik et al.....	642
The relation between the sugar content and weight of sugar beets, Novotný....	642
Recent chemical and physiological investigations on the sugar beet.....	642
Influence of light on the development of the sugar beet, Stift.....	642
[Manganese as a sugar-beet fertilizer], Zacharewicz.....	643
Report on sugar experiments, 1910-11.....	643
Timothy production on irrigated land in the Northwestern States, Evans.....	643
[Canada weeds and weed seed].....	643
The eradication of wild onion, Voelcker.....	643

## HORTICULTURE.

Library of agriculture.—Horticulture and truck farming, Skinner and McCredie.....	644
Plant-protection calendar for field, vineyard, orchard, and garden.....	644
Influence of fertilizers on the conservation of fruits, Espauillard.....	644
Profitable fruit storage cellar, Lewis.....	644
Orcharding in Maine, Gardner and Sweetser.....	644
How to make an orchard in British Columbia, Bealby.....	644
The Georgia apple, Hafer.....	644
Pruning olives in Italy, Pinto.....	644
The grape scions, or a sketch of the ampelography of Vaud, Burnat, and Anken.....	644
American stocks for Cape vineyards, Perold and Tribolet.....	645
Fruits of warm countries.—I, A general study of the fruits, Hubert.....	645
Manurial experiments on cacao in Trinidad, De Verteuil.....	645
The date palm ( <i>Phoenix dactylifera</i> ) in Egypt, Paoletti.....	645
The planting and care of shade trees.....	645
The pecan, Reed.....	645
Making a garden of perennials, Egan.....	645
Molding concrete flower pots, boxes, jardinières, etc., Houghton.....	645
Molding concrete fountains and lawn ornaments, Houghton.....	645

## FORESTRY.

Forestry in New England, Hawley and Hawes.....	646
Report on timber conditions around Lesser Slave Lake, Cameron.....	646
The forest trees of Britain, Johns, revised by Boulger.....	646
Notes on Kerry woods, Robinson.....	646
Yield tables for British woodlands and the finance of British forestry, Maw....	646
Taxation investigations.—III, The form of standing trees, Jonson.....	646
A method of investigating yields per acre in many aged stands, Chapman.....	647
Arrangement of silvicultural experiments and classes of yield tables, Vater....	647
Report of Forest Park Reservation Commission of New Jersey, 1911.....	647
Forest administration in eastern Bengal and Assam, 1910-11, Monro and Carter.....	647
Report on State nurseries and plantations for 1909-10, Kensington.....	647
Emory oak in southern Arizona, Phillips.....	647
Report on bamboo as material for production of paper pulp, Raitt.....	647
Rubber: Its culture and preparation, Wolf-Czapek.....	647
[Rubber in the Federated Malay States], Lewton-Brain.....	647
The excretion of serum from moist rubber after pressing, Zimmermann.....	648
Creosotes with special reference to protection of wood from decay, Winslow....	648
Bibliography of forestry published during 1911.....	648

## DISEASES OF PLANTS.

Relation of certain parasitic fungi to the host, Cook and Taubenhaus.....	648
The biology and morphology of <i>Kuehneola albida</i> and <i>Uredo mülleri</i> , Strelin....	648
Notes on some heteroecious rusts of Connecticut, Clinton.....	648
The development of <i>Glæosporium malicorticis</i> , Jackson.....	649

	Page.
The structure and development of crown gall: A plant cancer, Smith et al . . . . .	649
Crown gall on mangolds in England, Bilfen . . . . .	649
On two injurious fungi of garden plants, Köck . . . . .	649
Treatment of seed wheat for smut . . . . .	649
Trials of alleged preventives for smut in wheat . . . . .	649
The diseases of ginseng and their control, Whetzel and Rosenbaum . . . . .	649
An external dry rot of potato tubers, Jamieson and Wollenweber . . . . .	650
The relationship of <i>Oospora scabies</i> to the higher bacteria, Cunningham . . . . .	650
Biochemical research on leaf-roll of potato.—III, Chemical characters, Doby . . . . .	650
Treatment of seed potatoes with formalin . . . . .	650
Gummosis, De Bussy . . . . .	650
The Deli form of <i>Bacillus solanacearum</i> , Honing . . . . .	650
A serious root disease of radish, Barrett . . . . .	651
Tomato leaf rust . . . . .	651
Treatment of chlorosis in fruit trees and vines, Hiltner . . . . .	651
Oily or glassy fruits, Gross . . . . .	651
Experiments with fungi associated with leaf spot and canker, Lewis . . . . .	651
Some notes on <i>Spharopsis malorum</i> , Brooks and DeMerit . . . . .	651
Apple fruit spot and quince blotch, Brooks and Black . . . . .	652
Three destructive diseases of the peach, Essig . . . . .	652
Method of spreading of the olive knot disease, Horne, Parker, and Daines . . . . .	652
Experiments with sprays for controlling <i>Peronospora viticola</i> , Bretschneider . . . . .	652
The downy mildew fungi and their control, Bretschneider . . . . .	652
A knot of citrus trees caused by <i>Spharopsis tumefaciens</i> , Hedges and Tenny . . . . .	652
Citrus scab, Fawcett . . . . .	653
Notes on some diseases of trees in our national forests, II, Hedgcock . . . . .	653
The chestnut bark fungus, <i>Diaporthe parasitica</i> , Shear . . . . .	653
Some observations on experiments with the chestnut bark disease, Collins . . . . .	653
The chestnut bark disease in Massachusetts, Graves . . . . .	654
Observations on the chestnut bark disease in Pennsylvania, Rumbold . . . . .	654
Preliminary notes on a twig blight of <i>Quercus prinus</i> , Ingram . . . . .	654
Tannic acid as protection for oak wood against dry rot, Wehmer . . . . .	654
Bacterial black spot of walnut, Rodway . . . . .	654
<i>Peridermium cedri</i> as a destructive fungus, Troup . . . . .	654
Parasitism of <i>Phoradendron juniperinum libocedri</i> , Meinecke . . . . .	655
The use of fungicides to prevent damping off, Hartley . . . . .	655
The detection of inert ingredients of fungicides, Wallace and Evans . . . . .	655

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

Proceedings of the Seventh International Zoological Congress . . . . .	655
Proceedings of the First International Entomological Congress . . . . .	656
Insects injurious to corn, Fullaway . . . . .	656

# EXPERIMENT STATION RECORD.

VOL. XXVII.

NOVEMBER, 1912.

No. 7.

The 1912 convention of the Association of American Agricultural Colleges and Experiment Stations will long be remembered as one of the most interesting and inspiring annual gatherings of the association since its organization twenty-six years ago. Although the anniversary features stood out prominently, and there was a tracing of progress and a setting forth of what the establishment of these institutions has meant, the present-day problems did not lack for attention, and their consideration was characterized by a clearness of vision and a maturity of thought which showed the extent to which opinion has been crystallized on many fundamental lines of policy. A brief account of the convention will be given in a subsequent issue.

The three anniversaries observed this year commemorate the beginning of opportunity for agriculture in this country. Hence their special significance. It was in 1862, a half century ago, that the Morrill Act was passed donating public lands for industrial education, which marked the birth of the agricultural college in America; and it was in the same year that the National Department of Agriculture was founded at Washington. It was in 1887, a quarter century back, that the policy of federal aid for agricultural experimentation throughout the country was established. These three events are the most important from the standpoint of agriculture which this or any country has known. Out of them has grown the largest and most influential movement in education, the most highly developed department of agriculture, and the most comprehensive and efficient system of experiment stations to be found in any country.

Agriculture waited many centuries for such a recognition. It was a trade merely, conducted on the basis of experience and personal judgment, with only a hinted basis in science. It was unformulated as a teaching subject, the trade school being the only ideal in agricultural instruction, and there had been provided for it but slight means of acquiring knowledge except through empirical experience. For the most part it was guided by tradition, and it embraced an element of superstition, which ascribed important considerations to

the phases of the moon and the movement of other heavenly bodies. The idea that it involved much more than skill and intuition and brawn, or was teachable except as a practical art, or that experience and tradition could be extended and interpreted in the light of science, was new and restricted. It was only the farseeing who realized these possibilities. The farmers who had received a college education were not more successful than those who had not, for they found their education bore no relation to their business and they must go to school to the successful men of their neighborhood. Except for the broader vision it gave them, the influence of their education in advancing agriculture was negligible.

We have now become so accustomed to these three agencies for agricultural advancement, it would seem that their significance and great importance should always have been recognized. The struggle and opposition of a few years ago is lost sight of, and it is difficult to realize what an innovation their establishment marked. The review of the conditions under which these movements began, the history of their progress, and the measuring of their influence and position formed, therefore, matters of rare interest at the recent convention.

Such reviews were ably presented by Dr. W. O. Thompson for the land-grant colleges, Dr. A. C. True for the Federal Department of Agriculture, and Dr. H. C. White for the experiment stations. These papers, together with the presidential address of Dr. W. E. Stone and a paper by Dean Davenport on the American agricultural college, constituted the special anniversary features of the convention. By vote of the association these papers are to be printed separately from the proceedings for more extended distribution and use. Those relating to the land-grant colleges will here be considered, reserving for a future issue the anniversary of agricultural experimentation as embodied in the National Department of Agriculture and the American system of experiment stations.

In the presidential address of Dr. Stone and the historical paper of Dean Davenport, the history of these colleges was drawn upon to show something of the vicissitudes they have passed through, the dangers which still confront them, and the position they have attained in the field of education.

Dean Davenport characterized the history of the agricultural college as forty years of apparent failure and a dozen years of dazzling success. From the fact that the fundamental ideas underlying them were new and radical, they had to meet the conservatism of the older and well established institutions. In their early history they experienced an attitude of indifference, mistrust, and general lack of confidence. "Farmers did not believe in their principles. Edu-

cators regarded them as outside the sphere of educational recognition, and these attitudes were reflected by the general public." Further obstacles in the pioneer years were the undeveloped condition of science, the lack of a body of teachable knowledge, and the lack of trained teachers for industrial education. Even the experiment stations, which came after the barriers of prejudice had been partially broken down, were for a time received with scant confidence by either the public or by scientific men.

A large measure of credit was given the separate agricultural colleges for the success which has attended agricultural education in later years. These colleges for thirty or forty years withstood the brunt of the attack on this new education, worked out the ideals of the founders, and gradually developed the means and the system for teaching agriculture and secured recognition for it.

In the recent development of these institutions the constituency of the college has come to be the whole State, with provision for extension teaching and for agricultural research and demonstration. Their students have increased a thousand per cent in the last ten years, and at the same time the colleges have greatly advanced their standards. It was stated that in the case of the agricultural colleges connected with universities, fifty-five per cent of the graduates return to the land, and ninety-five per cent engage in some agricultural pursuit.

Now that the land-grant colleges have demonstrated their claim to an honorable place in the educational field, and have acquired prestige and public confidence, new opposition and jealousies have developed within the States as to the field they are occupying, the support to be given them, and other matters, giving rise to controversies which have threatened to disrupt them in some cases. This conflict between competing institutions Dr. Stone regarded as a matter of serious concern, calling for wise and liberal action. "In States where the land-grant college and state university are separated, no time should be lost by their authorities in arriving at an understanding as to the respective fields they are to occupy, always with reference to public welfare. Duplication of effort should be avoided for the sake of economy as well as harmony, and then good faith should be kept. The ideal adjustment between two such institutions is that which secures to the State, by coordination of both, the full range of instruction otherwise given in a single state university, without unnecessary duplication."

Failure to mutually agree upon an adjustment will inevitably bring legislative interference, and the possible clothing of a single board of regents with extraordinary power over the separate institutions. Particularly when the latter method is extended to interference with the internal administration, it was declared to be "destructive of the

spirit, the individuality, and the freedom so necessary to the life and progress of an educational institution."

Dr. Stone also referred to the attempts "to crystallize an interpretation of the Morrill Act to the effect that the land-grant colleges were intended to be of secondary grade—a kind of industrial and trade school; that agricultural instruction is *per se* of this order, and that 'mechanic arts' means trade and vocational training rather than engineering," an assumption which he found to be borne out by neither the law nor the facts.

"All of these difficulties, the struggle for recognition, the opposition of competing institutions, the attempts to segregate the colleges in an inferior class, were but to be expected under the circumstances. They constitute real obstacles and hindrances to progress in many cases. They might have been to a larger degree averted by concerted and positive action of the institutions in formulating their policies with regard to those things and defining their positions in advance."

Dr. Stone also discussed the situation growing out of the present extraordinary general interest in agriculture, which has brought demands on the college the result of which "is likely to be a weakening and letting down of the quality of its instruction and research." Although recognizing this popular awakening as one of the most encouraging movements of the day, he held that extension work demands the wisest guidance in order that it may find its right place and relation in the organization of our institutions. While promoting it and giving it true direction. "we should guard jealously our scientific workers and teachers from the distractions of extension enterprises. It is most certain that the future will demand more and more of our institutions; that much of the present extension work will prove only ephemeral; that the demand will be for more thorough teaching, serious investigations, and for a service which eventually can only be supplied by those who labor in the laboratory and class room rather than on the lecture platform. To prepare for this time we must increase rather than diminish the substantial scientific work in our stations and sound teaching in our colleges, as the reserve from which extension activities must always draw their inspiration and material."

Viewing broadly the work of these land-grant institutions, Dr. Stone declared that their establishment "has brought the application of scientific principles into the commonest occupations, emphasized the democracy of education, established the status of tax-supported institutions of higher learning, and, more than any other cause, contributed to the development of the new education. Now, at the end of fifty years, the land-grant colleges with the experiment stations and

the departments of agricultural extension constitute the most unique, useful, appreciated, and popular group of institutions in the country."

The influence of the Morrill Act upon American higher education, as presented by Dr. W. O. Thompson, was especially interesting because of the review it gave of the early efforts to secure federal aid for industrial education, the ideals developed by these institutions, and the scholarly deductions drawn as to the wider influences these colleges have had on education.

At the present time when these institutions have so abundantly justified themselves and the wisdom of their establishment, it is difficult to realize that the Morrill bill should have been opposed and vetoed on such grounds as its supposed effect on the relation of the federal and state governments, the effect on existing institutions, doubt as to whether it would promote the advancement of agriculture, and the contention that Congress could not appropriate money for education in the States and hence its aid by means of land grant was of doubtful constitutionality. A characteristic feature of the debate of that time, as Dr. Thompson pointed out, was the inconsistency of the position that public land could with propriety be donated for certain types of education (as had already been done in numerous instances), but the doubt as to the propriety of extending this aid to establishing institutions for agricultural education. The land-grant colleges have set at rest this doubt and proved the wisdom of federal aid to education.

As to the origin of the agitation for industrial education and the support it received, Dr. Thompson developed the interesting fact that "in the great agricultural States this movement was born and cherished among the progressive and prosperous farmers in the several communities." He showed this by many references to the reports of agricultural societies and meetings the country over. There was a widespread movement for a practical type of education which should relate more directly to the everyday life of the common people. "This new educational reform sprang not from the educational philosophers or the professional teachers, but from the rank and file of the people themselves." And having developed out of this desire, the land-grant colleges have taken it as their ideal "to teach all knowledge to all men."

This marks a sharp contrast between them and the class of institutions which aim to teach the essentials to prepared men. The needs of the people have been the guiding spirits for the land-grant institutions. The maintenance of conventional standards is not the central idea, but the liberal education of the industrial classes. Such a public-supported institution is to be operated "for the good it can

do, for the people it can serve, for the science it can promote, and for the civilization it can advance," a view of democracy in education which is now reflected in many other classes of institutions.

Furthermore, as Dr. Thompson pointed out, the colleges of agriculture and mechanic arts have constituted a great national movement for science in higher education. Their attitude toward science is one of the significant products of the Morrill Act. When science was struggling for recognition in the school programs of the country the land-grant institutions recognized that from the very terms of the law they were to teach the sciences related to agriculture and mechanic arts. While they have emphasized the economic phases of science, obviously applied science must follow pure science, and this has tended to broaden the scope of their field and teachings.

One effect of these colleges on the state universities with which they were associated was that the latter were "forced into a freedom hitherto unknown in higher education. This attitude toward science steadily influenced the attitude toward every other subject properly within the horizon of the university." As a result the state university "found itself free to teach in every field of human inquiry and to investigate any subject yielding knowledge."

The influence of the land-grant colleges upon higher education, viewed from their history of fifty years, and the real positions which these institutions have occupied in the educational world, was summed up by Dr. Thompson under the following heads:

(1) The land-grant colleges have clearly stimulated the interest of the people in higher education. "Apart from the education provided for the students, they have demonstrated their capacity for public service and have carried to the people an uplifting message."

(2) They have set a precedent for federal aid to education and proved the wisdom of it—of using a portion of the government's increasing revenues "for the purpose of developing a people able to sustain an efficient government."

(3) They have brought industrial education to its rightful place in the esteem of the American people, and have forced its recognition by all institutions for higher education.

(4) They have efficiently influenced the practical aims of higher education by insisting upon a larger liberty in the programs of education and in the contents of the course of study.

(5) They have stimulated investigation and research in many fields. "We can not be blind to the fact that very much of the investigational and research work of American higher education to-day finds inspiration in the achievements of these institutions."

(6) They have had an influence on the Government itself which has affected the cause of higher education. "The fact that government has become more humane, more beneficent, and almost philan-

tropic in many of its activities, is probably due to the humanizing influence of the educational activities supported and stimulated by the Government."

It is refreshing to have a liberal-minded, appreciative estimate of these institutions, based on an intelligent and intimate study of their activities and influence. It is inspiring, because it shows how large a factor they have actually been in the evolution of industrial education. The other side has often been presented, and, as if misrepresentation had become a habit, credit continues to be denied them, even when they have attained a high degree of success and the results are so much in evidence.

One critic who views the function of the agricultural colleges as that of training farmers, and hence argues for the trade school standard, has recently, in connection with a discussion of the proposed reorganization of a state institution, presented an elaborate argument in favor of an agricultural school pure and simple, maintaining that agricultural education can not be properly developed when associated with engineering. Again, a document has quite recently been issued giving the distribution of college and university graduates among the professions and various walks of life, including agriculture. This survey evidently takes a similar view of the scope of agriculture, for we read in the deductions from the analysis that "in spite of the comparatively large number of agricultural courses, farming does not attract and never has attracted a very large number of college graduates." It may be mentioned in passing that the list of institutions studied includes only three of the state universities of the central west having courses in agriculture, and not a single separate college of agriculture and mechanic arts. The largest quota of graduates entering farming from the colleges included in the analysis is reported as less than four per cent, in the years 1836 to 1840, a time when there were, of course, no agricultural courses in any American colleges. After this the deduction follows (from data ten years old or more for fully half the institutions) that "although the number of graduates entering agricultural pursuits is increasing, it is not increasing so rapidly as the number entering other professions. Consequently the curve for the college-bred farmer is falling."

It is hoped that some time we may have reliable statistics on the graduates of land-grant colleges, made on a basis which will show not only how many are going into farming as a business, but how many are entering the broader field which the agricultural colleges represent. Until we have this and a recognized distinction between the duty of these institutions toward farming as a trade, and toward the immeasurably broader field of agriculture as a great fundamental

industry, a condition under which a large share of the people live, a subject with its professional as well as its trade aspects,—until then the success of these colleges will continue to be measured by conflicting standards, often inadequate and unfair.

As President Stone well said: "One must know their history to appreciate their vigor and strength; must come in touch with the quality and character of their work; must grasp their scope and their relation to the life of the people, in order to comprehend their place in the educational world."

Fifty years is a short time as the world reckons time. It is a short time in which to bring about a new attitude toward education, to develop pedagogic methods suited to the needs of a new department of it, and to exert so vital an influence on higher education in general. It is a short time to lay the foundation for a science of agriculture, and supplant the rule of thumb by the rule of reason.

To-day nearly everyone recognizes the power and might of science, and nearly everyone pays it at least outward homage. The common laborer on the farm believes in its possibilities, just as does the manufacturer, the man of large business interests, and the housekeeper.

But this is a distinctly modern attitude. Only a half century ago the foundation of one of the institutions benefiting by the land-grant act was attacked on the ground that science is antagonistic to humanity. The contention was that science was unsuited to be an instrument of education because it dealt with nature rather than with man. To-day such a view would find scant support. Science is seen to be intensely human, and science in the service of man has become a watchword of progress. Half a century has demonstrated to the world something of the magnitude of its power to make for human betterment; and the most convincing and widely heralded illustrations of this have come through agriculture.

It is safe to say that no single factor has had a greater influence in bringing about this change in attitude than the agricultural investigation at these institutions, and their remarkable activity and success in popularizing science.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Technical methods of chemical analysis, edited by G. LUNGE ET AL., trans. and edited by C. A. KEANE ET AL. (*London, 1911, vol. 2, pts. 1, pp. XXVII+610; 2, pp. XII+611-1252, figs. 149*).—Among the subjects taken up in these parts of this work (E. S. R., 21, p. 105) are artificial manures, feeding stuffs, ammonia, and synthetic and naturally occurring organic dyes.

Solubility determinations in agricultural chemistry, A RINDELL (*Akad. Einladungsschr. Helsingfors, 1910, pp. 67; abs. in Jour. Soc. Chem. Indus., 31 (1912), No. 2, p. 87*).—This is a general discussion of solubility, its importance in agricultural chemistry, and the methods of determining solubility.

In experiments with Thomas slag it was found that the phosphoric acid was present apparently in a very insoluble form. "Experiments with pure water after 55 days' stirring at 25° C., using 10 gm. of substance per 1,000 gm. of water, show that with Thomas meal 0.1790 gm. of calcium oxid and 0.0316 gm. of phosphoric acid dissolve, whereas from raw phosphates the solution only takes up from 0.00075 to 0.0025 gm. of phosphoric acid, except in the case of Mexico phosphate, which is more soluble than Thomas meal. These phosphates will be perhaps slightly more soluble in soil solutions, but water is far preferable as a solvent in such cases to the 2 per cent citric acid usually employed, in which the soil constituents have too great a solubility. Stress is laid on the difficulties of finding solubility methods applicable to agricultural problems to which no theoretical objections can be raised, and the importance of introducing physical chemical methods into these conceptions is emphasized."

A modification of the diphenylamin test for nitrous and nitric acids, W. A. WITHERS and B. J. RAY (*Jour. Amer. Chem. Soc., 33 (1911), No. 5, pp. 708-711*).—This material has been noted from another source (E. S. R., 25, p. 804).

Determination of lithium, W. W. SKINNER and W. D. COLLINS (*U. S. Dept. Agr., Bur. Chem. Bul. 153, pp. 38*).—After a comprehensive review of existing methods for lithium, particularly in mineral waters, a modification of the Gooch method which has been developed and used in the Bureau of Chemistry is described. This method was found to be entirely satisfactory where weighable amounts of lithium were present.

Pyridin as a solvent for the lithium salts was found to be objectionable on account of its unpleasant odor, the difficulty of preparing and keeping it sufficiently free from water, and the fact that in water analysis usually very small quantities of lithium chlorid are to be separated from large quantities of sodium and potassium chlorid.

For the spectroscopic estimation of lithium the methods of Ballman, Bell, or Foehr, when modified to employ the alkalis as extracted by amyl alcohol, were found satisfactory. The quantitative spectroscopic method, however, is not deemed preferable to the Gooch method where weighable amounts of lithium are present.

**A method of estimating calcium carbonate in soils, H. S. SHREWSBURY** (*Pharm. Jour.* [London], 4. ser., 34 (1912), No. 2527, p. 394).—The method is as follows:

“Ten gm. of finely divided air-dried soil is treated with 100 cc. of roughly quarter-normal acetic acid, rotating the flask every time most of the soil settles, during 10 minutes. The same weight of soil is treated in the same manner with 100 cc. of distilled water. Twenty-five cc. of the filtrate from each extraction is evaporated in a platinum dish, ignited at a bright red heat for 30 minutes, and the residues of (principally) lime dissolved in 10 cc. or more if necessary of decinormal acetic acid. Titrating back with decinormal soda or potash and phenolphthalein gives the cubic centimeters equivalent to the lime in the residues. Subtracting the volume obtained from the control (which will not exceed 0.1 cc. in most soils), the remainder multiplied by 0.2 gives the percentage of calcium carbonate in the soil. The control experiment eliminates such bodies as the carbonates or organic salts of the alkalis, soluble organic calcium salts, calcium nitrate, etc. Acetic acid is chosen for the titration as it does not dissolve ignited iron oxid.”

The results of tests with 4 soils are also included.

**The estimation of ammonia in carbonated waters, G. D. ELSDON and N. EVERS** (*Pharm. Jour.* [London], 4. ser., 34 (1912), No. 2527, pp. 394, 395).—The presence of carbon dioxide in water seriously interferes with the determination of ammonia in such waters by the Nessler method. The following method will overcome much of the difficulty:

After shaking the flask containing the water by the usual method, 500 cc. is transferred to a distilling flask and 5 cc. or more of normal sulphuric acid, according to the alkalinity of the water, is added. An equivalent amount of normal sodium hydrate and a sufficient amount of sodium carbonate are then added and the usual procedure for determining free and albuminoid ammonia followed.

**Nitric nitrogen in mixed fertilizers, S. S. PECK** (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 11, pp. 817, 818).—The reliability of the modified Gunning and Kjeldahl methods for determining total nitrogen in a mixture containing an addition of nitrate of soda was studied.

The author believes on the basis of his findings with a new procedure, which is given below, that good results can be obtained with the Gunning method providing the moisture content of the sample is not too high. There was no loss of nitrogen noted in a mixed fertilizer containing sodium nitrate and sodium phosphate, which was kept for a period of 4 months. The method used is as follows:

Ten gm. of the fertilizer was transferred to a beaker and stirred with some water for about 1 hour. The mixture was then filtered, and the residue washed until a total bulk of 500 cc. of filtrate was obtained. Twenty-five cc. of the filtrate was then distilled with sodium hydrate for ammonia nitrogen, 25 cc. more reduced with iron and sulphuric acid for determining the nitric nitrogen, and a further 25 cc. used for determining the total nitrogen by the Kjeldahl method (using a 500 cc. flask with mercury, sulphuric acid, and potassium sulphate).

The nitrogen in the residue which remained on the filter paper was also determined but it was necessary first to render it air dry.

**Report of the committee on phosphate rock, W. D. RICHARDSON ET AL.** (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 10, pp. 783-787).—This is a report of the committee appointed by the division of fertilizer chemistry of the American Chemical Society on the analysis of phosphate rock. It includes the reports

of 3 subcommittees, on water, phosphoric acid, and iron and aluminum, and the work of 20 analysts.

**The forms of phosphorus in cotton-seed meal, J. B. RATHER** (*Texas Sta. Bul.* 146, pp. 3-16).—The preliminary portion of this work shows that fat in cotton-seed meal does not interfere with the extraction of the phosphorus compounds and their determination by the official volumetric method. Meal washed with ether yielded 0.213 per cent of phosphorus soluble in 0.2 per cent hydrochloric acid; unwashed meal 0.235 per cent. The lower results obtained when washing are thought possibly to be due to the extraction of lecithin.

Other tests showed that the phosphorus extracted by 0.2 per cent hydrochloric acid was much lower than the published results for water-soluble phosphorus. The phosphorus not extracted from meal by 0.2 per cent hydrochloric acid could not be precipitated by acidifying the alkaline (ammonia) extract with hydrochloric acid. The method of Forbes et al. (*E. S. R.*, 23, p. 303) was not found to include any appreciable amounts of meta- and pyrophosphoric acids in the determinations of inorganic phosphorus.

“The phosphorus soluble in 0.2 per cent hydrochloric acid was about 25 per cent of the total phosphorus. The inorganic phosphorus (Forbes method), in the samples of cotton-seed meal examined was less than 5 per cent of the total phosphorus. The phosphorus in the hydrochloric acid extract of cotton-seed meal capable of being precipitated by magnesia mixture and not soluble in acid alcohol was about 16 per cent of the total phosphorus. After extraction with 0.2 per cent of hydrochloric acid the phosphorus remaining was insoluble in water but nearly completely soluble in 0.2 per cent ammonia. Magnesia mixture precipitated most of the phosphorus extracted by ammonia. Practically all of the phosphorus was precipitated from the aqueous extract of cotton-seed meal by lead subacetate and by copper acetate. The principal compounds containing phosphorus were separated, which give the same reaction as those relied upon for proving the presence of meta- and pyrophosphoric acid. We have no evidence that the samples of cotton-seed meal examined contain either pyrophosphoric acid or metaphosphoric acid.”

See also a previous note by Crawford (*E. S. R.*, 23, p. 8).

**Lutein obtained from egg yolks, R. WILLSTÄTER and H. H. ESCHER** (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 76 (1912), No. 2-3, pp. 214-225, pl. 1; *abs. in Chem. Abs.*, 6 (1912), No. 6, p. 761).—The coagulum obtained by treating with alcohol yolks from 6,000 eggs, which weighed 110 kg., when extracted with acetone gave an extract containing lutein. The cholesterol and lecithin were precipitated from the acetone solution with petroleum ether, and 4 gm. of crude lutein was obtained by crystallizing from the concentrated petroleum-ether solution. With the exception of the melting point, which was between 192 and 193° C., the substance simulated xanthophyll. It differed from carotin in that it was more soluble in ethyl and methyl alcohol.

**Soy-bean oil, H. MATTHES and A. DAHLE** (*Arch. Pharm.*, 249 (1911), No. 6, pp. 424-435; *abs. in Jour. Soc. Chem. Indus.*, 30 (1911), No. 18, p. 1124).—“Soy-bean oil contains 94 to 95 per cent of fatty acids (present as glycerol esters), of which about 15 per cent consist of saturated acids (palmitic acid) and about 80 per cent of liquid unsaturated fatty acids. The latter were found to consist of about 70 per cent of oleic acid, about 24 per cent of linolic acid, and about 6 per cent of linolenic acid. Samples of the oils labeled ‘purified’ and ‘unpurified’ had the following characters, respectively: Specific gravity at 15° C., 0.9260, 0.9265; solidifying point, -11.5° C., -12° C.; refractive index at 40° C., 1.4680, 1.4680; acid value, 5.7, 1.71; saponification value, 192.3, 194.3; iodine value (Hübl, after 18 hours' action), 131.3, 132.6; Reichert-Meissl value, 0.75, 0.75;

Poleuske value, 0.78, 1.08; claidin reaction, positive. Exposure of the oil for 6 months (in daylight) to moist air increased the acid value but lowered the iodine value. Pure oxygen both in the absence and presence of moisture had no influence on the iodine value."

Valuation of tea, A. A. BESSON (*Chem. Ztg.*, 35 (1911), Nos. 88, pp. 813-815; 90, pp. 830-832; *abs. in Analyst*, 36 (1911), No. 426, p. 454).—These are the results of examining about 90 samples of tea, 43 of which were Chinese tea, while the remainder were from Ceylon, Java, and India. In the investigation particular stress was placed upon the stem or stalk content of the samples, but the work shows that very little relation exists between the amount of stalk and the price and quality of the tea as determined by the tasting test. It was noted, however, that Java tea which is grown at an altitude of 4,500 ft. was much better in quality than that grown at an altitude of 1,800 ft.

*Analyses of 90 samples of tea.*

Kind of tea.	Moisture.	Stalk.	Ash.	Caffein.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Chinese green tea.....	6.00-7.69	0.4-5.3	4.88-7.46	2.13-3.22
Chinese Foochow.....	6.29-9.06	4.1-17.5	4.80-5.73	2.23-3.64
Chinese Hankow.....	6.48-8.33	8.6-17.1	4.95-5.65	2.65-3.64
Ceylon tea.....	4.57-8.12	5.8-43.4	4.54-5.65	2.80-4.10
Indian tea.....	4.00-8.08	11.5-37.4	4.72-5.64	3.31-4.15
Java tea.....	8.22-10.50	4.4-29.9	5.53-7.32	2.22-4.54

Researches on the nature of enzym action.—II. The synthetic properties of antiemulsin, W. M. BAYLISS (*Jour. Physiol.*, 43 (1912), No. 6, pp. 455-466).—"The intraperitoneal injection of emulsin does not give rise to the production of any true antienzym, although precipitins for the proteins contained in the solution are produced. The inhibitory action of such immune serum on the action of emulsin *in vitro* is no greater than that of normal serum, as was also found by Cöca, and is merely due to diminution of the optimal acidity. Neither normal nor immune serum is capable of synthetic action. Emulsin, on the other hand, will synthesize lactose and also the glucosid of glycerol. This synthesis by the enzym is retarded by the presence of serum, presumably owing to diminution of acid reaction. Incidentally it is shown that emulsin is not of protein nature."

The determination of crude fiber in finely powdered materials, W. GREIFENHAAGEN (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 3, pp. 101, 102).—The determination of crude fiber in materials like powdered cotton seed, cocoa, etc., by the König method presents several difficulties, notably as to the time required for the filtration process. The author recommends the use of a Buchner nutsche apparatus, 10.5 cm. in diameter, which contains a thin layer of asbestos fiber to serve as a filter, or, if a nutsche is not obtainable, a perforated porcelain plate may be substituted in filtering the undiluted hot fluid. The residue can be washed on the filter without any trouble. The author was able in a period of 2 hours to make 8 crude fiber determinations.

In regard to the determination of lecithin, P. SALZMAN (*Apoth. Ztg.*, 26 (1911), No. 91, p. 949; *abs. in Chem. Ztg.*, 36 (1912), No. 9, *Repert.*, p. 37).—Glikin's method (*U. S. R.*, 22, p. 410) was found to give the best results.

The flocculation of lecithin and lecithin protein mixtures with acids, J. FEINSCHMIDT (*Biochem. Ztschr.*, 38 (1912), No. 3-4, pp. 244-251).—Aqueous suspensions of lecithin preparations possess optimum flocculation points in a definite hydrogen ion concentration. This concentration is a very strong acid

one and lies between  $10^{-2}$  and  $10^{-4}$ , and depends upon the lecithin preparation under examination. Neutral salts were found to cause an even greater turbidity of the suspension, but had the disadvantage of inhibiting the flocculating process and changing the optimum.

By mixing lecithin and protein together a new complex is produced which at first flocculates very markedly but later causes only turbidity in the optimum points for pure lecithin. This, according to the author, is the first time in which it has been shown that a colloid, sensitive to an acid, may be influenced by the addition of another colloid.

**Estimation of minute amounts of arsenic in foods**, E. CLARK and A. G. WOODMAN (*U. S. Dept. Agr., Bur. Chem. Circ. 99, pp. 7, figs. 3*).—A modification of the Marsh-Berzelius method as applied to the estimation of minute amounts of the arsenic in foods is described. The method makes use of the form of apparatus devised by Bishop for the determination of arsenic in sulphuric acid.<sup>a</sup> In the method standard mirrors are prepared for comparison. Antimony, when present in the material under examination, must be removed before testing.

**Honey and its analysis**, F. MUTTELET (*Ann. Falsif., 4 (1911), No. 30, pp. 192-196*).—This is a bibliography of the literature in regard to the chemistry of honey. See also a previous note (*E. S. R., 25, p. 109*).

**Examination of marmalades and milk chocolates**, HÄRTEL (*Chem. Ztg., 34 (1910), No. 141, p. 1256; abs. in Chem. Abs., 6 (1912), No. 6, p. 781*).—“The author prefers to filter off the insoluble matter, wash, dilute the filtrate to a definite volume, and analyze aliquot parts of this. For milk chocolate, the Baier and Neumann method is recommended, also the determination of the Reichert-Meissl number, which with a 10 per cent milk addition is 2.8 to 3, with 20 per cent 5.6 to 6.”

**Cider vinegar**, F. E. MOTT (*Jour. Indus. and Engin. Chem., 3 (1911), No. 10, pp. 747-750*).—This is a description of a method which has for its purpose the detection of certain forms of adulteration in cider vinegar which are being practiced at the present time. It depends upon the relation of levulose and dextrose in pure cider vinegar as calculated from the percentage of reducing sugars present, expressed as dextrose, and the polariscope reading in degrees Ventzke as observed in the 200 mm. tube.

**The detection of benzoic acid in coffee extract**, H. C. LYTHER and C. E. MARSH (*Jour. Indus. and Engin. Chem., 3 (1911), No. 11, p. 842*).—“Make the solution acid and extract several times with ether. Wash the combined ether extracts with water and extract with ammonia. Evaporate the ammoniacal extract to a small volume, adding ammonia from time to time to prevent it from becoming acid, and add a solution of manganese sulphate. Filter through a small filter, wash with as little water as possible, and add ferric chlorid to the filtrate, when a dark greenish precipitate will occur if benzoic acid is present. Evaporate to dryness in the casserole in which the precipitation was made, and sublime by placing an inverted funnel covered with a filter paper in the dish and heating over an asbestos gauze. Remove the funnel and determine the melting point of some of the crystals which, if benzoic acid, should be  $121.4^{\circ}$  C. The rest of the crystals may be dissolved in ammonia, the excess of ammonia evaporated and ferric chlorid added, when the characteristic flesh-colored precipitate will occur if benzoic acid is present.

“For quantitative purposes the method of Edmund Clark<sup>b</sup> was employed with good results, as the natural reacting substance has but little influence.”

<sup>a</sup> *Jour. Amer. Chem. Soc.*, 28 (1906), No. 2, pp. 178-182.

<sup>b</sup> *Science*, n. ser., 30 (1909), No. 764, pp. 253, 254.

**Spirit of nitrous ether.** H. H. HANSON and A. K. BURKE (*Maine Sta. Bul.* 201, pp. 147-158, fig. 1).—The factors bringing about the deterioration and decomposition of spirit of nitrous ether, commonly called sweet spirits of niter, were studied. A sample of the product kept in strict accordance with the directions given by the United States Pharmacopœia maintained constant strength for 60 days and decreased only slightly the next 30 days. Under less favorable conditions decomposition began at once and steadily continued.

When determining the amount of ethyl nitrite in spirit of nitrous ether by liberating the nitrogen dioxid and measuring the gas in the nitrometer, the volume did not become constant in from 30 to 60 minutes' time as one would be led to suppose by the directions given in the Pharmacopœia, but was found to increase slowly and at a varying rate, and was influenced by various factors. It is not deemed practicable to attempt to obtain an absolutely constant volume nor to apply a factor as a correction for the last traces of gas. A modified method of analysis, for which better results are claimed than with either the old or new Pharmacopœia methods, is described. The modified method is considered more economical in time and reagents, and can be more easily manipulated.

**Use of saponin for homogenizing samples of milk to be examined.** A. FROUIN (*Ann. Chim. Analyt.*, 16 (1911), No. 12, pp. 454, 455; *abs. in Chem. Abs.*, 6 (1912), No. 6, p. 781).—It often happens that milk samples destined for examination after standing for several months can not be properly homogenized by shaking, etc. If bile is added to such milk a uniform suspension can be obtained, but the mixture putrefies very easily. When saponin is added to milk previously neutralized to litmus with ammonium hydroxid in amounts of 0.005 gm. to 100 cc. of milk, and the mixture is heated from 40 to 56° for 10 minutes amid frequent shaking, a well homogenized mixture is obtained which will not interfere with the analytical results.

**A new method for determining fat and salt in butter, especially adapted for use in creameries.** R. H. SHAW (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 202, pp. 8, fig. 1).—The procedure consists of melting the butter at 100° F., mixing it thoroughly with a spatula or spoon and weighing off 20 gm. in a small beaker, transferring the melted butter to a special form of separating funnel of known weight with the aid of water, centrifuging in a Babcock centrifuge about 1 minute, drawing off the water containing the salt and then dissolving the curd with dilute sulphuric acid (9 cc. of cold water and 11 cc. of sulphuric acid). After centrifuging again for 1 minute the acid solution containing the curd is drawn off and the separatory funnel containing the fat is weighed. The separatory funnel and the special form of socket for holding it in the centrifuge are illustrated. Results obtained in the test compared reasonably well with those given by the official method.

The washings from the above test are used for determining the salt content, by estimating chlorin with a volumetric solution of nitrate of silver (14.525 gm. per liter), using a 10 per cent potassium chromate solution as the indicator. If the moisture content of the sample is known the percentage of curd can be found by difference.

**The index of refraction of the mixed acids of fatty oils.** W. B. SMITH (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 1, pp. 36-38; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 3, p. 139; *Sciucc.*, n. ser., 35 (1912), No. 897, p. 381).—"The relation between the refraction of the oil and the refraction of the acids depends upon the percentage of acid in the glycerids, being nearly independent of the total refraction and of the iodine value."

The ratios between the refraction of oils and their insoluble acids were determined. For linseed, cod-liver, soy-bean, corn, rape-seed, cotton-seed, pea-

nut, and olive oils, the figure fluctuated between 0.9933 and 0.9947, while for oleo oil, lard, lard stearin, oleostearin, cacao butter, palm-nut oil, butter (renovated), coconut oil, and a mixture of cotton-seed oil and oleostearin it was between 0.9923 and 0.9941.

The above figures are in accord with those which can be calculated from published refractive indexes and with the ratio of the refraction of fatty acids and triglycerids. The saturation of the acid has little effect upon the ratio, which is 0.9938 for stearin, olein, linolin, and linolenin, and with the lower acids a decrease, as with palmitin 0.9922 and laurin 0.9905.

Some typographical errors in reference books are pointed out, particularly in regard to the refractive index usually published for the insoluble acids of olive and rape oils and cacao butter. Olive oil is said to be low by about 0.005.

Coconut fat with a high iodine number, W. VAUCEL (*Ztschr., Öffentl. Chem.*, 18 (1912), No. 3, pp. 46, 47).—The findings were practically the same as those of Richardson, previously noted (E. S. R., 26, p. 611).

Abnormal beeswax, G. BUCHNER (*Ztschr. Öffentl. Chem.*, 18 (1912), No. 5, pp. 90, 91).—A discussion of the analytical results obtained with beeswax of known (East African, Italian, and Spanish) and unknown origin. In most cases it was noted that where the free acidity was normal or slightly higher there was a diminution in the ester figure and an increase in the hydrocarbon content.

In regard to the separation of organic phosphorus compounds of feedstuffs, G. FINGERLING and A. HECKING (*Biochem. Ztschr.*, 37 (1911), No. 5-6, pp. 452-456).—Stutzer's method (E. S. R., 20, p. 173) utilizes nitric acid for dissolving the precipitate obtained with calcium chlorid and ammonium hydroxid and reprecipitates with molybdate. According to the results of this work the method can be employed only for the separation of inorganic phosphorus from lecithin, casein, nuclein, and sodium nucleate, and not when phytin is present.

With appropriate modifications in the method it may be possible to extend its use to the examination of plant materials containing phytin.

The determination of moisture content of beet seeds, H. PLAIN (*Centbl. Zuckeriudus.*, 19 (1911), No. 46, pp. 1549, 1550, fig. 1; *abs. in Chem. Abs.*, 6 (1912), No. 6, p. 812, fig. 1).—The usual method utilized for this purpose consists of drying 5 gm. of the seed balls for at least 14 hours to constant weight. This, however, does not include colloid water. If these samples are weighed directly in the oven, illustrated in the original article, the time of drying can be reduced to from 5 to 6 hours.

"Experimental work showed that the time could not be shortened by subdividing the sample and heating higher, for some of the 'colloid water' was driven off. The decrease in weight of 5 gm. after 60 minutes was in proportion to the amount of water in the sample. A table was constructed, as the average of a large number of determinations, showing the decrease in weight after 30 minutes and 60 minutes and the respective percentages of water. The moisture content should be taken when constant weighings are first observed, generally after 110 to 125 minutes, according to moisture content."

A chemical-technical vade mecum for sugar refineries, A. GRÖGER (*Chemisch-Technisches Vademecum für Zuckerfabriken. Prerau, vols. 1, 1901, pp. XVI+573; 2, 1906, pp. XV+344; Brünn, vol. 3, 1911, pp. XII+697*).—This is a digest of the literature pertaining to the chemo-technology of the sugar industry. The literature from 1851 to 1910 is considered.

The carbohydrate constituents of Para rubber; separation of l-methyl-inositol, S. S. PICKLES and B. W. WHITEFIELD (*Proc. Chem. Soc. London*, 27 (1911), No. 383, p. 54; *Bul. Imp. Inst. [So. Kensington]*, 10 (1912), No. 1, pp. 25-27).—A sample of Para rubber was found to have a very high percentage of

acetone-soluble substances, which are usually reported collectively as resin. On making a close examination of the so-called resinous substances it was found that 2.7 per cent of them consisted of a carbohydrate which was identified as l-methylinosit.

In regard to helianthus tubers for alcohol production, J. VON HÉRICS-TÓTH and A. VON OSZTROVSZKY (*Kísérlet. Közlem., 1½ (1911), No. 4, pp. 589-594*).—From the results obtained by analysis and laboratory fermentation tests with helianthus tubers (*Helianthus doronicoides*), it seems that this is a good source of raw material for producing alcohol. The refuse also contains a high fat and protein content, and is considered more nutritious than potato slops obtained from distilleries for feeding stock.

Annual reports of the progress of chemistry for 1911, edited by J. C. CAIN and A. J. GREENAWAY (*Ann. Rpts. Prog. Chem. [London], 8 (1911), pp. IX+319*).—This publication deals with the progress made in general, physical, inorganic, organic, analytical, physiological, agricultural, and mineralogical chemistry, vegetable physiology, and radioactivity during the year 1911.

Proceedings of the twenty-eighth annual convention of the Association of Official Agricultural Chemists, edited by H. W. WILEY and ANNE L. PIERCE (*U. S. Dept. Agr., Bur. Chem. Bul. 152, pp. 268, figs. 4*).—This is the official report of the proceedings of the convention held at Washington, D. C., Nov. 20 to 22, 1911, a summarized account of which has been previously noted (*E. S. R., 26, p. 97*).

### METEOROLOGY—WATER.

Monthly Weather Review (*Mo. Weather Rev., 40 (1912), Nos. 5, pp. 659-813, pls. 10, fig. 1; 6, pp. 815-976, pls. 9, figs. 6*).—In addition to the usual climatological summaries, weather forecasts and warnings for May and June, 1912, notes on the application of upper-air observations to weather forecasting for May and June, 1912; river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology, a condensed climatological summary, and climatological tables and charts, these numbers contain the following special papers:

No. 5.—May, 1912, Flood in Michigan, by F. H. Coleman; The Effect of the Time of Observation on Mean Temperatures, by C. A. Donnel; The Annual Rainfall and Temperature of the United States, by G. A. Lindsay; Unusual Hailstorm, Wichita, Kans., by R. H. Sullivan; Snow Survey on Pole Creek Watershed, Sanpete County, Utah, by B. F. Eliason; Notes on the Rivers of the Sacramento and Lower San Joaquin Watersheds during May, 1912, by N. R. Taylor; Notes on the Streams of the Upper San Joaquin Watershed, by W. E. Bonnett; and Studies in Frost Protection, Effect of Mixing the Air (illus.), by A. G. McAdie.

No. 6.—Special Notes on the Weather in Florida during June, 1912, by A. J. Mitchell; Severe Storms of June 16, 1912, by J. M. Kirk; Drainage of American Bottoms, by C. J. Root; Tornado in Southwest Missouri, June 15, 1912, by G. Reeder; Electric Storms in Western Kansas, by S. D. Flora; Flood in the Colorado, by F. H. Brandenburg; Snow Slides and Slips (illus.), by L. Peugeot; Some Effects of Surface Slope on Climate, by J. C. Alter; Notes on the Rivers of the Sacramento and Lower San Joaquin Watersheds during June, 1912, by N. R. Taylor; Notes on the Streams of the Upper San Joaquin Watershed, by W. E. Bonnett; Weather at Point Reyes Light, Cal., during June, 1912, by J. Jones; Preserving Mammie Caprifigs from Frost, by G. P. Rixford; Heating the Atmosphere, by A. G. McAdie; Convenient Conversion Table for Frost Work, by A. G. McAdie; Severe Local Storm at Pocatello, Idaho, by A. R.

Teepie; Mammatocumulus Clouds (illus.), by W. J. Humphreys; Unusual Hailstone Formation (illus.), by D. J. Lingle; and Hail in the Tropics.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and H. W. ANGLIER (*Massachusetts Sta. Mct. Buls.* 283, 284, pp. 4 each).—Summaries of observations\* at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July and August, 1912. The data are briefly discussed in general notes on the weather of each month.

Annual report of the director of the [Philippine] Weather Bureau for the year 1908, J. ALGUÉ (*Ann. Rpt. [Philippine] Weather Bur., 1908, pt. 3, pp. 276*).—A record of meteorological observations at the secondary stations in 1908.

The influence of climatic conditions on the agricultural industry of Germany, A. SCHNIDER (*Landw. Hefte, 1912, No. 1, pp. 27*).—This is a brief general discussion of the subject.

The conservation of snow, J. E. CHURCH, JR. (*Sci. Amer. Sup., 74 (1912), No. 1914, pp. 152-155, figs. 11*).—This article describes apparatus and methods used by the Nevada Station in studying the influence of forests in conserving snow on mountains.

It was found that snow tanks or gages were inefficient because of high winds, but that the snow could be quickly and accurately measured by means of the snow sampler described. By means of evaporation measurements it was possible to make allowance for the loss of moisture due to this cause. The only factor left undetermined was that of absorption by the soil. This is "roughly determined for given localities by subtracting the stream flow from the net moisture content of the snow field; that is, the moisture content after due allowance has been made for evaporation. . . ."

"The seasonal survey is now being extended to the study of the relation of typical slopes to each other to determine a method of forecasting the probability and magnitude of floods.

"There can no longer be any question of the direct influence of forests in delaying the melting of the snow and thus in retarding stream flow at the very time when floods normally occur. It is also equally true that forests, if too dense, fail to attain their maximum efficiency as conservers of snow. On the other hand, the planting of timber screens at strategic points on exposed slopes will greatly increase their capacity to store more snow."

Drinking water supply of primitive people, A. HABERLANDT (*Mitt. Justus Perthes' Geogr. Anst., 1912, Ergänzungsh. 174, pp. VI+57*).—The subject is discussed mainly from the anthropological standpoint and with special reference to the arid regions of the earth.

## SOILS—FERTILIZERS.

Soils of the eastern United States and their use, XXXVIII-XL, J. A. BONSTEEL (*U. S. Dept. Agr., Bur. Soils Circs. 65, pp. 15; 68, pp. 21; 69, pp. 14*).—These circulars discuss the following soil types:

Circular 65, Muck and Peat.—As defined, peat consists of nearly pure, partially decayed remains of vegetable tissue. Muck consists of such material mingled with an appreciable amount of extraneous mineral matter. It is also more completely disintegrated than peat in most cases. Of such areas, nearly 1,000,000 acres have been surveyed and mapped by the Bureau of Soils.

The installation of proper drainage is the first step in the utilization of these soils for crop production. Primarily the soils are best suited for the production of special purpose crops, but considerable areas are used for the growing of general farm produce. Among the special purpose crops which have been grown

with success are cabbage, onions, celery, lettuce, spinach, carrots, beets, turnips, and peppermint. Applications of potash and phosphatic fertilizers, and with many crops lime, have been found especially profitable. Coarse stable manure has also been used to advantage.

Circular 68, Meadow.—The term meadow is here used to designate “those low-lying, frequently somewhat swampy areas found along stream courses and tidewater embayments, which are subject to overflow and which are chiefly devoted to pasturage and the production of hay, when used for agricultural purposes, though usually occupied by trees and dense undergrowth when in their natural condition.” Meadow areas of this classification have been surveyed and mapped by the Bureau of Soils in 173 areas in 31 States, aggregating a total of 3,086,829 acres.

The necessity for protection of these soils from overflow and for drainage is pointed out. “In the more northern States the production of grass for mowing or pasturage is the chief use made of the cleared meadow areas. Corn, oats, and market-garden crops are also produced. In the Piedmont Plateau region meadow constitutes some of the best corn soils of the region.” In the Southern States the areas are partly devoted to cotton, corn, sugar cane, Bermuda grass, lespedeza, and vegetables, with a growing tendency toward corn and grass production. In the Central and north Central States these soils constitute important grass, corn, and wheat lands.

Circular 69, Marsh and Swamp.—The term swamp is here used to designate all areas which in their natural condition are too wet for the production of any crop. The word marsh designates low, wet, treeless areas usually covered by standing water and supporting a growth of grass and rushes. The marsh is subdivided into fresh water and tidal marshes. Soils of these classes have been surveyed and mapped by the Bureau of Soils to the extent of 2,355,240 acres.

The soils of these areas are well charged with organic matter and may be mucky or peaty. Drainage is the first requisite for their agricultural utilization. In the Middle Atlantic States these soils, when reclaimed, are well suited for the production of corn, cotton, and hay. Some of the tidal marsh areas are devoted to the production of rice of a high quality. In the central prairie States the reclaimed swamp lands constitute some of the most fertile and productive of the corn, oat, wheat, and grass lands.

The soils of Tripoli, P. VINASSA DE REGNY (*Coltivatore*, 58 (1912), Nos. 1, pp. 4-8; 2, pp. 38-42, fig. 1; 3, pp. 70-73, figs. 3; 4, pp. 101-105, fig. 1; 5, pp. 135-138, fig. 1; 6, pp. 166-170, fig. 1; 7, pp. 197-201, figs. 2; 8, pp. 231-236, figs. 2; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 6, pp. 1272-1275).—This is an account of observations on the typical soils of Tripoli, viz. the oasis sand, the desert sand, and the soils of Cyrenaica.

The oasis sand is stated to be very fertile. The soil is decidedly sandy, being composed of about 12 per cent gravel (over 1 mm. in diameter), 15 per cent coarse sand ( $\frac{1}{2}$  to  $\frac{3}{4}$  mm.), with about 90 per cent of the remainder of colloidal character. Of the soil material 46 per cent is soluble in hydrochloric acid. The carbonates form about 43 per cent of the soil.

The desert sand lies between the coast and the Jebel. The sand particles of this soil exceed 71 per cent, whereas the colloidal material is below 29 per cent. Scarcely 6.5 per cent of the soil is soluble in hydrochloric acid. This soil differs from the oasis sand in having a smaller percentage of coarse constituents and of calcium carbonate. The proportion of these constituents, however, increases gradually with the length of time that the soil has been under cultivation, the calcium carbonate being as high as 44 per cent in the older gardens and as low as 2.5 per cent in the newer gardens.

The rainfall in this section is too small to produce chemical decomposition in the soil. It is believed that the possibilities are excellent for utilizing the waters, which are retained under the sand by an impervious clay formation and afford an abundant and easily accessible supply of water.

Cyrenaica contains large areas of red soils of a clayey nature and high water-retaining power. The organic constituents varied from 3.9 to 8.3 per cent; potash from 0.14 to 0.83 per cent; phosphoric acid from 0.11 to 0.79 per cent; and nitrogen from 1 to 1.5 per cent.

**Researches on properties of peat soils of Picardy, E. COQUIDÉ** (*Recherches sur les Propriétés des Sols Tourbeux de la Picardie*. Paris, 1912, pp. 180, pls. 9, figs. 24; abs. in *Bul. Soc. Nat. Agr. France*, 72 (1912), No. 6, pp. 507-509; *Rev. Gén. Sci.*, 23 (1912), No. 16, pp. 641, 642).—This is an account of investigations on the character of the vegetation and the chemical and physical properties of these soils.

It is stated that the vegetation of large areas of these peat lands is similar to that of arid regions. This peculiarity is attributed to the fact that, although the absorptive power of the soil for water is enormous, the water is not given up to the plants until the point of saturation is reached. The soils are in very poor physical condition and are also deficient chemically.

**Black soils (chernozem), P. KOSSOVICH** (*Die Schwarzerde (Tschernosiom)*. Vienna, Berlin, London, 1912, pp. 156+VIII, figs. 20).—This has already been noted from another source (E. S. R., 26, p. 812).

**Gray sand and ortstein, H. NIKLAS** (*Naturw. Ztschr. Forst u. Landw.*, 10 (1912), No. 7, pp. 369-379).—This is a summary of the present knowledge on the formation and composition of ortstein and gray sand.

**The chemical composition of red saline clay, E. MARCUS and W. BILTZ** (*Ztschr. Anorgan. Chem.*, 77 (1912), No. 1, pp. 119-123).—Detailed analyses of samples of red clay obtained from Schönebeck are compared with the chemical composition of blue clays from the same source and of clays from various other sources. The characteristic difference in color of the Schönebeck clays is shown to be due to the differences in amount and form of iron present.

**A peculiarity of the mole, H. M. GMELIN** (*Cultura*, 24 (1912), No. 287, pp. 277-279).—The author found that the calcium carbonate content of the subsoil transported by moles to the surface was much higher than that of the surface soil. This led him to believe that the results of hydrochloric acid tests of the lime requirements of soils may be unreliable if the sample of soil happens to be taken from a mole hill, and this may be unavoidable owing to the smoothing over of the hills by mechanical agencies.

**The cause of the absorbent power of soils, U. PRATOLONGO** (*Staz. Sper. Agr. Ital.*, 45 (1912), No. 1, pp. 5-54; abs. in *Chem. Zentbl.*, 1912, I, No. 13, p. 1048).—This article gives in some detail the results of studies of the action of saline solutions on zeolites, leucite, and soils. Among the more important conclusions reached is that the absorptive power of soils can not be explained by the formation of solid solutions. See also a previous note (E. S. R., 25, p. 21).

**A method of retaining water in the soil, K. KREBS** (*Illus. Landw. Ztg.*, 32 (1912), No. 32, p. 307; abs. in *Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 6, p. 1280).—Comparative tests of different methods of planting crops with a view of holding the maximum amount of snow and thus increasing the water supply in the soil are reported.

**The cooperation of organisms in clay formation, P. ROHLAND** (*Biochem. Ztschr.*, 39 (1912), No. 3-4, pp. 205-207; abs. in *Jour. Chem. Soc. [London]*, 102 (1912), No. 595, II, p. 484).—"The odor of certain clays, which can be removed by ferric saccharate solutions, suggests to the author the possibility that clay may owe its formation to the action of micro-organisms."

The flocculating power of some soluble salts on the clay substances of the soil, G. MASONI (*Staz. Sper. Agr. Ital.*, 45 (1912), No. 2, pp. 113-159; *abs. in Chem. Zentbl.*, 1912, I, No. 18, p. 1496; *Jour. Soc. Chem. Indus.*, 31 (1912), No. 10, p. 504; *Jour. Chem. Soc. [London]*, 102 (1912), No. 597, II, pp. 677, 678).—“From the results of a large number of experiments the author concludes that chlorids have a greater flocculating power than nitrates and sulphates. Calcium salts are more active than potassium and ammonium salts, and the latter are more active than sodium salts. There appears to be no simple relation between the quantity of a salt and its flocculating power, but the flocculating power of the solution of a salt depends upon the ionic concentration and the degree of dissociation. . . .

“The flocculating power is a function of the cation, the anion being without influence. The flocculating power depends upon the valency of the cation, but not upon its atomic weight. If the value of the flocculating power for the sodium ion be taken as 1, then for the potassium or ammonium ion it is 2.4 and for the calcium ion 5.7. The flocculating power of a salt on the clay substance of a soil is directly connected with the absorptive power of the soil for the salt, and may be regarded as due to an interchange of radicals between the salt and the soil.”

Biochemical studies on soils subjected to dry heat, F. J. SEAVER and E. D. CLARK (*Biochem. Bul.*, 1 (1912), No. 3, pp. 413-427, pl. 1).—A study of extracts from soils subjected to different temperatures showed that the color and soluble matter varied with the temperature but not with the length of time of heating. The growth of oats was slightly increased in soils heated at low temperatures, 90 to 120° C., but was retarded progressively as the temperatures increased above this point.

“Retardation seems not to be due to the toxic effects of the substances rendered soluble, but to the fact that they are present in such large quantities that the plant is unable to absorb them. The influence of heated soils on the growth of fungi is the opposite of that on the growth of green plants, the growth becoming more luxuriant as the temperature is increased. This can be explained by the fact that fungi, unlike most green plants, have the power of adapting themselves to nutrient media of a comparatively high degree of concentration. The beneficial or harmful results, therefore, of the heating of a soil for the growth of plants depends upon the temperature to which the soil has been heated as well as upon the nature of the soil and the plant. The preference of certain plants for burned-over areas or for peaty soils may be explained by the acidity of such situations, a supposition we are testing by blueberry-culture experiments now under way.”

Bacterial slimes in soil, R. GREIG-SMITH (*Proc. Linn. Soc. N. S. Wales*, 36 (1911), pt. 4, pp. 609-612; *Centbl. Bakt. [etc.]*, 2. Abt., 34 (1912), No. 8-9, pp. 226, 227).—This note briefly presents evidence which is thought to indicate the presence of bacterial slimes in soils.

The determination of Rhizobia in the soil, R. GREIG-SMITH (*Proc. Linn. Soc. N. S. Wales*, 36 (1911), pt. 3, pp. 492-503; *Centbl. Bakt. [etc.]*, 2. Abt., 34 (1912), No. 8-9, pp. 227-229).—A medium specially suited to this purpose is described.

The rôle of *Streptothrix* in the soil, A. FOUSEK (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 1 (1912), No. 2, pp. 217-244).—Determinations of the number of *Streptothrix chromogena* and *S. alba* in different soil types and studies of the assimilation of nitrate, ammoniacal, and amid nitrogen, and free nitrogen of the air by these organisms and their effect on the decomposition of peptone, dried blood, bone meal, and straw, and on the growth of plants are reported.

The results show that *Streptothrix* composed from 20 to 30 per cent of the micro-organisms in loam soils, from 8 to 15 per cent in clay soils, and from 7 to 10 per cent in sands. Fallow soils contained larger numbers than cultivated soils. The organisms were also abundant on roots of *Aspidium*, *Quercus*, *Ulmus*, Gramineæ, and Papilionaceæ, and on decaying plant débris.

*Streptothrix* decomposed peptone, blood, bone meal, and straw, splitting off large quantities of ammonia. For culture purposes media containing milk sugar and grape sugar were especially well adapted. Cellulose may also be used as a source of carbon. The optimum temperature for the development of the organisms was 20° C., although there was a good, but very slow, development at lower temperatures.

*Streptothrix* produced no nitrification. On the other hand, there was strong reduction of nitrates to nitrite, but without direct denitrification, i. e., without loss of free nitrogen.

In view of the ready assimilation of nitrates, ammonium compounds, urea, and uric acid, it would appear that these organisms are instrumental to a prominent degree in fixing the nitrogen of fertilizers and soils and thereby diminishing the loss from denitrification. There was no assimilation of free nitrogen by *Streptothrix*, but the presence of these organisms did not diminish the assimilative capacity of *Azotobacter* for free nitrogen.

*Streptothrix* had a favorable effect on the growth of certain plants. This may be regarded as being due to the rapid decomposition of the organic matter whereby plant nutrients, especially assimilable nitrogenous compounds, are set free. It would also seem that these organisms aid in the production of nodules on Papilionaceæ.

The agrificere and the bacteriotoxins of the soil, R. GREIG-SMITH (*Proc. Linn. Soc. N. S. Wales*, 36 (1911), pt. 4, pp. 679-699; *Centbl. Bakt. [etc.]*, 2. Abt., 34 (1912), No. 8-9, pp. 224-226).—The author reports experiments which led him to believe that the chief reason for the increased bacterial activity in soils following antiseptic treatment with such fat solvents as chloroform, ether, etc., is the removal of the fatty protective covering of the soil particles (agrificere) referred to in a previous article (*E. S. R.*, 25, p. 525).

Beneficial effect of creatinin and creatin on growth, J. J. SKINNER (*Bot. Gaz.*, 54 (1912), No. 2, pp. 152-163, fig. 1).—In water cultures with wheat seedlings creatinin and creatin increased growth both in presence and in absence of nitrate. These substances were apparently able to replace nitrates in plant growth. They also increased the assimilation of phosphoric acid and potash.

Partial sterilization of soil, R. B. McBRIDE (*Pharm. Jour. [London]*, 4. ser., 34 (1912), No. 2527, p. 381; *abs. in Chem. Abs.*, 6 (1912), No. 15, pp. 2127, 2128).—It is reported that the growth of sweet peas was increased by sprinkling the soil with a solution of potassium permanganate, 2 oz. to 25 gal. of water. The solution was also effective in destroying the green fly on rose bushes.

Partial sterilization of soil for greenhouses, E. J. RUSSELL and F. R. PETHERBRIDGE (*Pharm. Jour. [London]*, 4. ser., 34 (1912), No. 2524, pp. 286, 287).—This is an abstract of an article already noted from another source (*E. S. R.*, 26, p. 815).

Clearing heavy lands as adapted to Montaja and Panendjoan, E. VAN LENNEP (*Teyssmannia*, 23 (1912), No. 4, pp. 211-229, pls. 4).—The author describes a so-called ditching system of clearing, cultivating, and aerating land overgrown with dense second growth of shrubbery and grasses and isolated trees. The method is stated to be extensively and successfully used in the preparation of land for the cinchona plant in different sections of Java.

Reclamation of crawfish lands, W. D. GARRISON (*South Carolina Sta. Bul.* 167, pp. 12, pls. 10).—The term crawfish lands is taken to represent the lower

coastal region of South Carolina. In order to determine the agricultural value of these lands, experiments were made at the coast substation near Charleston during 1909 and 1910 in tile draining and the production of different vegetables, oats, corn, and cotton under applications of various fertilizer mixtures and materials. The drainage system was planned and partly installed by the Office of Experiment Stations.

The results showed a marked profit from all the crops grown on the drained land. Lime in conjunction with a complete fertilizer was especially beneficial.

"The theory held by some people that the drainage of this land was impracticable, and that even if the water could be successfully removed the land would not be productive, has been entirely overthrown by the record of the past 2 years."

**Sponge spicules in swamp soils.** R. O. E. DAVIS (*U. S. Dept. Agr., Bur. Soils Circ. 67, pp. 4, fig. 1*).—Microscopic examinations of swamp soils of Georgia showed a large number of spicules, the remains of fresh-water sponges, in the surface 6 in. of soil. These spicules were found to cause irritation of the feet of animals. *Marcenia millsii* was the most common of the spicules. Examinations of other soils from different parts of the United States showed only small quantities of spicules of a variable character. Applying soil free from spicules, as by mixing in some of the subsoil, is suggested as the most practical means of overcoming the difficulty.

**Sponge spicules in certain soils.** R. O. E. DAVIS (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 15 (1912), Sect. VII, pp. 77-79*).—See above.

**Present status of fertilizer investigations.** F. K. CAMERON (*Amer. Fert., 37 (1912), No. 2, pp. 31-33*).—This is a brief review in which it is maintained that "the present status of fertilizer investigations, both theoretical and practical, is one of unrest and doubt."

**Some secondary actions of manures upon the soil.** A. D. HALL (*Agr. Gaz. Tasmania, 20 (1912), Nos. 2, pp. 54-59; 3, pp. 81-84; 4, pp. 144, 145; 5, pp. 182-188; 6, pp. 215-218*).—The more important points discussed in this article are summarized as follows:

"The long-continued use of sulphate of ammonia on soils poor in lime results in the soils becoming acid. The acidity is caused by certain microfungi in the soil which split up the sulphate of ammonia in order to obtain the ammonia, and thereby set free sulphuric acid. The infertility of such soils is due to the way all the regular bacterial changes in the soil are suspended by the acidity; instead, fungi permeate the soil and seize upon the manure. The remedy, as may be seen upon the Woburn plats, is the use of sufficient lime to keep the soil neutral. From the Rothamsted soils carbonate of lime is being washed out at the rate of 800 to 1,000 lbs. per acre per annum, the losses being increased by the use of sulphate of ammonia, but lessened by dung or nitrate of soda. Nitrate of soda, when applied to heavy soils in large quantities, destroys their texture. Some of the nitrate of soda gets converted into carbonate of soda by the action of plants and bacteria, and carbonate of soda, by deflocculating the clay particles, destroys the tilth. The best remedies are the use of soot or superphosphate, the best preventive is the use of a mixture of nitrate of soda and sulphate of ammonia instead of either separately. Soluble potash manures and common salt may also injure the tilth of heavy soils through the production of a little soluble alkali by interaction with carbonate of lime in the soil. The remedy is to apply such manures in the winter or in conjunction with superphosphate."

A biological method of preserving manure, C. BARTHEL and S. RHODIN (*Deut. Landw. Presse*, 39 (1912), Nos. 59, pp. 583, 584; 51, pp. 597, 598).—In previous experiments (E. S. R., 18, p. 918) one of the authors showed that the loss of ammonia from manure could be reduced by setting up lactic-acid fermentation in the manure. In further tests of the method, here reported, it was found that the addition of from 50 to 100 liters of whey to 1,000 kg. of manure (sprinkled on each layer) greatly reduced the loss of ammonia from the manure. The fertilizing efficiency as determined in experiments with potatoes, beets, oats, and rye was only 59 per cent as great for the untreated as for the treated manure.

Certain relations between the ash constituents of various fertilized plants, G. LEONCINI (*Staz. Sper. Agr. Ital.*, 45 (1912), No. 1, pp. 55-75; *abs. in Chem. Zentbl.*, 1912, I, No. 13, p. 1949).—This is a preliminary report giving the results of a considerable number of analyses of plants fertilized in different ways, from which the author concludes that phosphoric acid is taken up by the plant most readily in presence of calcium and magnesium salts, less readily in the presence of potash salts.

Utilization of atmospheric nitrogen, T. H. NORTON (*U. S. Dept. Com. and Labor, Bur. Manfr., Spec. Agents Scr.*, 1912, No. 52, pp. 178, figs. 5; *abs. in Daily Cons. and Trade Rpts.*, [U. S.], 15 (1912), No. 149, p. 1309).—This monograph describes in detail the present supply of nitrogen, and the scientific and technical features of the various processes which have been proposed for the production of ammonia and nitric acid from the air, as well as the technical and commercial aspects of the new industry which has been established through the practical application of certain of these processes. A short chapter is also devoted to the question of the utilization of coal waste and peat as sources of ammonia. A bibliography of the more important papers on the subject is given at the end of the report.

Discussing the possibilities of employing the new processes under American conditions, the author emphasizes the following points:

"The synthetic production of nitric acid from the atmosphere is a highly specialized process, dependent for the time being on exceptionally cheap sources of electricity. Many are laboring upon the problem of increasing the output per unit of electric power. Such experiments are most advantageously conducted in connection with the gigantic plants in Scandinavia.

"The case is different with cyanamid. Here is a product that can be easily produced wherever calcium carbide is manufactured. Its value as a fertilizer becomes more manifest each year. The items of its cost are easily controlled. It is a material from which our stock of cyanids can be economically produced. At present we send abroad annually \$750,000 for various cyanids. It is susceptible of application on a large scale in gold mining. In 1910 imports of cyanamid reached \$40,000, so that evidently its use in agriculture is recognized. The establishment of cyanamid works at several points on American soil, where water power is relatively cheap and earnest propaganda in connection with the employment of the new fertilizer in farming would constitute an important step in freeing our country from dependence upon foreign sources of combined nitrogen.

"The same may be said to some extent, but with considerable reserve, in regard to aluminum nitride. The manufacture of the compound involves even less power than that of cyanamid, and the transformation of the combined nitrogen into the form of ammonia is less expensive than in the case of cyanamid. Granting the correctness of the claims made in favor of this latest

nitrogen industry, the United States is certainly one of the countries specially favored for the establishment of the manufacture, as it possesses fairly extensive deposits of bauxite, the mineral serving for the fixation of nitrogen. There is much to warrant American enterprise in studying very closely the possibilities of this new industry. It promises to furnish ammonium compounds far more economically than any existing process and involves a simpler plant than that required for cyanamid or air nitrates. . . .

"It will be noted that at present the methods of producing ammonia and ammonium compounds, more particularly the staple product, ammonium sulphate, seem to offer the larger field for the economic fixation of atmospheric nitrogen. The more complete utilization of the nitrogen present in coal, peat, etc., increases likewise the available supply of ammonia. In view of this trend in the general movement, coupled with the prospective depletion of the stock of Chile saltpeter, it is eminently desirable that steps should promptly be taken to ascertain, as nearly as possible, under what conditions and to what extent ammonium sulphate can satisfactorily replace Chile saltpeter for the most important crops.

"There is much diversity of opinion on this point, both in Europe and America. Some authorities assign to nitrogen in the form of ammonia a general value as fertilizer equal to that of nitrogen in the form of saltpeter. Others assign a lower value. Market quotations fluctuate, following naturally the laws of supply and demand, but frequently they show a higher valuation of ammonia nitrogen than of nitrogen in the form of nitrate. More definite data on this subject might aid naturally the plans of American investors in handling projects for establishing on American soil adequate plants for the domestic production of combined nitrogen.

"In conclusion it can be regarded as beyond doubt that the present achievements of applied chemistry in this field render it possible for American industry and American agriculture to face the threatened exhaustion of the nitrate deposits of Chile and the demands attendant upon a rapidly growing population without any feeling of apprehension. The processes already perfected and described in detail show that there is no early danger of a nitrogen famine. The continual perfection of the processes and the appearance at frequent intervals of novel additional methods, as well as the popularization of the new forms of combined nitrogen, all point to a steady movement forward, and to the assurance that combined nitrogen, as an industrial product, will be furnished on an increased scale without advance in cost above existing rates as fast as the demand is evident."

**The fixation of atmospheric nitrogen by the use of aluminum nitrid,** F. MARRE (*Génie Civil*, 61 (1912), No. 2, pp. 30-33; *abs. in Chem. Abs.*, 6 (1912), No. 15, p. 2130).—The theory and the practical operation of this method of fixation of free nitrogen are described. A product is obtained which is not a definite compound, but contains about 31 per cent of nitrogen.

**The behavior of commercial calcium cyanamid in storage and under the influence of soils and colloids,** G. HENSCHEL (*Das Verhalten des technischen Calcium-cyanamids bei der Aufbewahrung sowie unter dem Einfluss Kulturböden und Kolloiden. Diss. Leipzig, 1912, pp. 72; abs. in Centbl. Bakt. [etc.], 2. Abt., 34 (1912), No. 10-13, pp. 279, 280*).—The author found that the decomposition of cyanamid was somewhat more rapid in dry sterilized soils and colloids than in those which contained micro-organisms. There was almost complete agreement between the intensity of cyanamid decomposition in sterilized media and ammonia formation in media containing micro-organisms. This was true for practically all soils experimented with except a humus moor sand rich in colloids and showing feeble bacterial activity. It was shown that the

humus of the soil was of special importance in connection with the cyanamid decomposition. There was an active formation of urea in cyanamid in storage, but no loss of nitrogen was observed.

Further investigations on lime nitrogen, C. J. MILO (*Meded. Proefstat. Java-Suikerindus.*, 1912, No. 16, pp. 427-527, pls. 6, fig. 1; *Arch. Suikerindus. Nederland. Indië*, 20 (1912), Nos. 15, pp. 431-472, pl. 1, fig. 1; 16, pp. 481-539, pls. 5).—This is a continuation of work previously noted (E. S. R., 25, p. 826). The results of the whole investigation are summarized in the abstract below.

Lime nitrogen as regards its transformation in the soil, C. J. MILO (*Meded. Proefstat. Java-Suikerindus.*, 1912, No. 20, pp. 601-634; *Arch. Suikerindus. Nederland. Indië*, 20 (1912), No. 27, pp. 1039-1072; *abs. in Chem. Zentbl.*, 1912, II, No. 16, p. 1393).—Previous investigations by the author (see above) dealt with the question of the transformation of lime nitrogen in storage. The present report gives an account of experiments to determine the transformation processes, fertilizing value, and effect of this material in the soil under Java conditions. A light and a heavy soil type were used in the experiments. The more important results of these studies are summarized as follows:

The lime nitrogen absorbed moisture and carbon dioxide from the atmosphere. Under such conditions there was a loss of nitrogen by volatilization. By storing the material under dry conditions the loss of nitrogen was reduced to a minimum. Calcium cyanamid during storage formed various decomposition products which depended to a more or less extent on the time, humidity of the atmosphere, and the temperature.

In heavy soils the fertilizing value was less for the old than for the new product, and for this reason the Kjeldahl method did not give a true estimate of the fertilizing value of the material.

Cyanamid was much less readily soluble in water than ammonium sulphate. Less cyanamid than ammonia was absorbed by the soil.

The transformation of lime nitrogen varied considerably as between heavy, strongly absorbent soils containing colloidal and catalytic substances and light, less absorbent soils. In the first type of soil the transformation was in two consecutive stages—(1) the production of cyanamid followed quickly by urea and (2) the formation of ammonium carbonate from the urea. The first is due to a chemico-physical action, whereas the second is most probably brought about by micro-organisms. The ammonia was readily absorbed by the heavy soil.

In case of the light soil the calcium cyanamid formed basic calcium cyanamid salts and free cyanamid. These compounds remained stable in the soil and were slowly transformed into ammonia, this slowness of transformation giving a chance for the production of dicyandiamid. The toxic action of lime nitrogen in light soils when the fertilizer is applied at the time of seeding was due to the presence of the cyanamid in the soil in its unchanged condition. Cyanamid was strongly toxic to plants.

Dicyandiamid, even in large amounts, did not prevent the germination of seeds. In the later stages of growth of the plants dicyandiamid had a tendency to cause a temporary drying of the tips and edges of the leaves.

In the heavy, strongly absorbent soils rich in colloidal and catalytic substances the toxic action of the cyanamid was lessened largely by the hydrolysis of cyanamid to urea. In case of the light soils with little colloidal and catalytic substances, the hydrolysis of the cyanamid may be prevented and polymerization to dicyandiamid may take place. A thorough covering and careful distribution of the lime nitrogen in the soil and an intimate contact of the colloidal and catalytic material with the calcium cyanamid tend to expedite the necessary transformation of the cyanamid to urea.

On the basis of the foregoing investigations the author makes the following practical suggestions:

Lime nitrogen is not adapted for top dressing or to acid soils and can not be recommended for light soils of low absorbent power.

Unusually heavy applications can not be recommended. In order to avoid dusting, it is recommended that the fertilizer be mixed with soil, though in some cases where there is little or no wind this may not be necessary.

Lime nitrogen should not be mixed with soluble phosphatic fertilizers, but mixing with potash salts is allowable if desired. The fertilizer should be applied from 4 to 14 days before seeding, the shorter periods being recommended for the heavy soils, with a longer period of time on light soils. It is recommended that the fertilizer be immediately and carefully covered and well mixed with the soil. In view of the fact that cyanamid is less readily absorbed than ammonia, heavy applications of water are not desirable until the transformation of the cyanamid to ammonia has taken place.

**New observations on the behavior of nitrate in cultivated soil.** J. VOGEL (*Cenubl. Bakt. [etc.], 2. Abt., 37 (1912), No. 18-22, pp. 549-561; abs. in Chem. Ztg., 36 (1912), pp. 1104, 1105; Jour. Soc. Chem. Indus., 31 (1912), No. 20, p. 1000; Chem. Abs., 6 (1912), No. 23, p. 3785*).—Previous investigations having shown that there was a loss of free nitrogen from ammoniacal and nitrate nitrogen added to soils receiving calcium carbonate (E. S. R., 26, p. 226), the author made further studies to determine the influence of aeration of the soil on such loss of nitrogen from nitrates, using per 100 gm. of soil 0.32 gm. of sodium nitrate and 0.9 gm. of calcium carbonate. The water content of the soil was kept constant during the experiment and the soil was placed in shallow layers in porcelain dishes and frequently stirred to provide aeration.

The results of the first series of experiments seemed to indicate that the loss of nitrogen in the transformation of the nitrates might be due to evaporation of water from oversaturated soil particles. In later trials, however, the evaporation of water from the soil was controlled, but still there was loss of free nitrogen. This loss occurred in all cases where the original water content of the soil was kept constant for a considerable time during the course of the experiment. A water content of about 15 per cent was sufficient to bring about the transformation. The soil changed in its physical appearance, becoming dry and powdery after a few days.

Apparently the nitrates were transformed suddenly and with great energy, and the resulting sodium carbonate brought about the changed appearance of the soil. The transformation process is thought to be a purely chemical one in which the nitrate nitrogen is in part reduced to lower oxids of nitrogen.

**Influence of organic substances on the decomposition and action of nitrogenous compounds.** GERLACH and DENSCHE (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 4 (1912), No. 4, pp. 259-317*).—In pot experiments with a loamy soil moderately supplied with organic matter it was found that the addition of easily decomposable organic compounds, such as grape sugar or straw, resulted in the conversion of soluble nitrogen salts, like ammonium sulphate and sodium nitrate, into insoluble protein compounds, which, however, were later readily decomposed and assimilated by plants. In soil receiving no applications of organic matter there was a distinct gain in total nitrogen in 2 months. With additions of grape sugar, straw, ammonium sulphate, and sodium nitrate the results were variable and inconclusive in this respect.

**The action of lime nitrogen and calcium nitrate in the field.** GERLACH (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 4 (1912), No. 4, pp. 318-353*).—In field experiments with oats, rye, and potatoes lime nitrogen proved distinctly inferior and commercial calcium nitrate about equal to sodium nitrate.

The phosphate deposits of the United States, W. H. WAGGAMAN (*Amer. Fert.*, 37 (1912), No. 2, pp. 34-36).—This is a brief description of the phosphate deposits of the United States, with notes on their exploitation.

The composition of certain Palestine phosphates and their fluorin content, G. DANELLI (*Rend. Soc. Chim. Ital.*, 2. ser., 4 (1912), No. 7, pp. 165-173).—Reports by other investigators on these phosphates are reviewed, and detailed analyses of a number of samples are presented. These show from 25.5 to 39.28 per cent of phosphoric acid and from 3.5 to 4.88 per cent of fluorin. The amount of calcium carbonate present varies widely, ranging from 1.87 to 33.73 per cent. The peculiar characteristics and geological relationships of these phosphates are briefly discussed.

The utilization of the phosphates of central Russia (*Internat. Inst. Agr. [Rome]. Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 6, pp. 1286-1290).—This is a brief summary of information on this subject with a number of references to the literature.

It is stated in brief that "in central and eastern Russia there are extensive phosphate deposits sufficient for the needs of that part of the country. These minerals, though not rich enough to interest directly the international market, do so indirectly, because when industrially prepared they might emancipate the above regions from the importation of foreign phosphatic manures. The utilization of the above phosphates is important also from the point of view of international agricultural production, for by favoring the consumption of manures, which at present is hampered by the cost of carriage, it promotes the development of agriculture in these important cereal and flax producing regions."

[Experiments with different phosphates], D. N. PRYANISHNIKOV ET AL. (*Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscow)*, 18 (1912), No. 1, pp. XIII+1-179, figs 17).—Accounts are given of experiments in the preparation of superphosphates from different Russian phosphorites, and of tests of the fertilizing value of various kinds of crude and manufactured phosphates.

It was found in general that certain of the Russian phosphorites could be economically converted into superphosphate. The crude phosphates showed a low fertilizing value when used on sandy soils. Superphosphates and precipitated phosphates prepared from the crude phosphates, however, showed a decidedly higher fertilizer efficiency. So-called Viborg phosphate, prepared from various crude phosphates (by fusion with sodium carbonate), proved more effective than phosphatic slag.

Tests of the treatment of steamed bone and crude phosphate with potassium bisulphate indicated that this method may replace the use of sulphuric acid in the manufacture of superphosphates from bones and natural phosphates. The addition of iron bisulphid to crude phosphate was found to decrease the yield. Additions of small amounts of ferrous and ferric sulphates were without effect, but larger amounts were injurious. The addition of ammonium chlorid favored the solution of the phosphate, and mixtures of ammonium chlorid and sodium nitrate were more effective in this respect than sodium nitrate alone. With the most favorable combination the yield was very nearly as great as with superphosphate. Mixtures of calcium nitrate and ammonium sulphate exerted very favorable action on crude phosphates, Thomas slag, and bone meal.

In experiments with oats the addition of peat exerted no favorable effect upon the assimilation of the phosphates.

Field investigations for potash in America, H. S. GALE (*Amer. Fert.*, 37 (1912), No. 2, pp. 38-40).—A brief summary is given of the work undertaken and the results obtained by the United States Geological Survey in its search for potash supplies in this country.

Alunite as a source of potash, W. H. WAGGAMAN (*U. S. Dept. Agr., Bur. Soils Circ. 70, pp. 4, figs. 2; Orig. Commun. S. Internat. Cong. Appl. Chem. [Washington and New York], 15 (1912), Sect. VII, pp. 375-379, figs. 2*).—This circular describes the method and apparatus used to determine the temperature at which complete decomposition of alunite takes place. It was found that at a temperature of 700° C. alunite is completely decomposed, yielding a residue of potassium sulphate and alumina. The alunite used in these experiments contained 26.88 per cent of sulphur trioxid over and above that required to combine with the potash present. Only 23.05 per cent, however, was recovered on ignition, indicating a considerable loss as sulphur dioxid at the high temperature of ignition used. The ignited residue contained 15.95 per cent of potash and 15.37 per cent of sulphuric acid (SO<sub>2</sub>). It is estimated that a ton (2,000 lbs.) of pure alunite will yield 220 lbs. of potash, 1,090 lbs. of sulphuric acid, and 740 lbs. of aluminium, worth in the aggregate \$13.88.

In view of the difficulty and expense of leaching potassium sulphate from the ignited material, it is thought to be "more practical to use the ignited alunite (free from soluble aluminum compounds) directly as a fertilizer either alone or in mixed goods, since the expense of separating the soluble salts from the alumina would probably more than counterbalance the value of the alumina obtained. The percentage of potash in the ignited residue is considerably greater than in kainit, our chief source of soluble potash."

The extraction of potash from silicate rocks, W. H. ROSS (*U. S. Dept. Agr., Bur. Soils Circ. 71, pp. 10; Amer. Fert., 37 (1912), No. 4, pp. 44-49*).—This article describes and discusses the relative efficiency of various processes which have been proposed for this purpose. It is stated that "on account of its simplicity the method of decomposing feldspar by heating with calcium carbonate and with calcium chlorid (or sodium chlorid) could undoubtedly be carried out on a large scale without involving any serious mechanical difficulty, and the method would thus be a practical one providing the value of the products obtained would compensate for the expense involved," but the author is of the opinion "that any method to be economical must produce at the same time other products of value in addition to the potassium."

Action of magnesium [and manganese] fertilizers and of boric acid, P. ANDOUARD (*Engrais, 27 (1912), No. 29, pp. 796-799*).—Experiments on a variety of crops with a basic magnesium fertilizer with manganese (manganese carbonate) and with boric acid gave as a rule inconclusive results. The only fact which appeared to be definitely determined was that such fertilizers should not be applied broadcast, but should be thoroughly mixed with the soil.

Studies on catalytic fertilizers, E. BOULLANGER (*Ann. Sci. Agron., 4, ser., 1 (1912), I, No. 3, pp. 161-180; Ann. Inst. Pasteur, 26 (1912), No. 6, pp. 456-466; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 9, pp. 1955, 1956*).—In pot experiments with manganese chlorid, alone and combined with other fertilizing materials, it was found that the use of the manganese fertilizer resulted in a marked increase in the yield of potatoes, but was practically without effect on barley. In similar experiments with so-called manganose and lime manganate, it was found that the manganese fertilizers increased the yield of oats, peas, and clover to a marked extent, particularly in the presence of potash salts and of a complete fertilizer containing potash.

Experiments are also reported in which manganese sulphate was compared with aluminum sulphate, sodium silicate, ferrous sulphate, uranium sulphate, and flowers of sulphur on a variety of vegetables. The effect of these substances was variable, but in the majority of cases the yield was increased. The action of flowers of sulphur was especially favorable.

On the basis of these experiments the author classifies the catalytic fertilizers as specially favorable to each crop as follows: Carrots, sulphur, aluminum sulphate, manganese sulphate, sodium silicate; beans, sulphur; celery, sulphur, ferrous sulphate, sodium silicate, manganese sulphate, aluminum sulphate; spinach, sulphur; lettuce, sulphur, manganese sulphate, ferrous sulphate, aluminum sulphate; sorrel, sulphur, manganese sulphate; chicory, sulphur, aluminum sulphate; potatoes, aluminum sulphate, sodium silicate, ferrous sulphate, sulphur; onions, aluminum sulphate, ferrous sulphate, and sulphur.

From experiments with sulphur on sterilized and unsterilized soil, the author concludes that the favorable action of sulphur is probably due to its influence in modifying the bacterial flora of the soil and hindering the growth of certain organisms.

The stimulating action of manganese, QUANTE (*Deut. Landw. Presse*, 39 (1912), No. 83, pp. 961, 962).—This article briefly reviews the work of several investigators on this subject, especially that of Boulanger noted above.

The author concludes that the experimental results show a marked benefit under certain conditions from the use of manganese compounds as fertilizer, but that some of the conclusions regarding the agricultural value of these compounds are too optimistic. Their actual agricultural value can be finally determined only by further practical trials under farm conditions.

Study of sulphur as a fertilizer, F. GIANNETTO (*Bol. Quind. Soc. Agr. Ital.*, 17 (1912), No. 17, pp. 425-429).—Experiments with sulphur alone and combined with different fertilizing materials on potatoes are reported, showing that sulphur applied alone at the rate of 400 lbs. per acre resulted in a net loss. When applied with other fertilizers, there was a decided net profit.

Utilizing sludge in Bradford, England (*Municipal Jour.*, 32 (1912), No. 19, pp. 708, 709).—Brief reference is made to profits obtained from sewage grease and sludge fertilizer, the plant for the preparation of which is being greatly extended.

City street sweepings as a fertilizer, J. J. SKINNER and J. H. BEATTIE (*U. S. Dept. Agr., Bur. Soils Circ.* 66, pp. 8, figs. 2; *Jour. Indus. and Engin. Chem.*, 4 (1912), No. 8, pp. 604-606, figs. 2).—This circular reports analyses and wire-basket tests on wheat, corn, and radishes of 3 samples of street sweepings. (1) the debris secured by hand sweeping with a brush, (2) that secured by sweeping with a machine, and (3) the decomposed material from a dump pile which had been accumulating for some time. The first contained 1.34 per cent nitrogen, 0.71 per cent potash, and 1.03 per cent phosphoric acid; the second, 0.86 per cent nitrogen, 0.55 per cent potash, and 0.55 per cent phosphoric acid; and the third, 0.60 per cent nitrogen, 0.56 per cent potash, and 0.60 per cent phosphoric acid.

In general, increased growth followed the use of all 3 materials, but the decomposed sweepings were least effective. The fertilizing effect of the sweepings was increased by extraction of the oil which they contained, and after such treatment they were practically as effective as stable manure. It appears, therefore, that oil is a deleterious constituent of the sweepings.

Review of progress in the fertilizer industry, 1909-1911, G. WICHERN (*Chem. Ztg.*, 36 (1912), Nos. 37, pp. 329-331, figs. 3; 39, pp. 354, 355, figs. 2; 43, pp. 389-392, figs. 6; 46, pp. 420, 421, figs. 5; 47, pp. 434-436, figs. 5; 51, pp. 474, 475; 52, pp. 482-484).—This is a review of statistics of production and consumption of fertilizers in the principal countries of the world, of development of old and new sources of fertilizing materials, of methods of analysis, and of manufacturing processes and machinery.

[Fertilizers] (*Fla. Quart. Bul. Agr. Dept.*, 22 (1912), No. 2, pp. 159-169, 173-185).—This is a report on fertilizer inspection in Florida, with analyses of fertilizers examined to April 1, 1912.

## AGRICULTURAL BOTANY.

A comparison of the alterations in the velocity of growth of certain seedlings through the action of rapid and slow electrons of the  $\beta$ -rays of radium, also a comparison of the rôle of chemical make-up and of physical factors in determining these alterations, E. D. CONGDON (*Arch. Entwickl. Mech. Organ.*, 34 (1912), pt. 2, pp. 267-280, figs. 2).—A study was made of the growth-retarding effects upon small seeds of the rapid and slow electrons of the  $\beta$ -radiations and also of the relative importance of physical factors and of chemical composition in determining the sensitiveness of seeds to exposures to radium. Five kinds of seeds were used, viz. black mustard, millet, poppy, Nicotiana, and Anarantus.

It was found that by changing the penetrating power of the electrons their effect was greatly modified. The embryos of mustard and millet were chiefly affected, from which it is inferred that the embryo appeared more sensitive than the stored foodstuff. It is thought probable that in the embryo there was some injury of ferments or some unfavorable change of the general conditions of solution rather than the breaking down of certain compounds which retarded the growth.

The slower electrons of the  $\beta$ -radiations were found to have a greater retardating action than the more rapid ones in proportion to their ionizing power, and in proportion to their energy content on the small seeds used in the experiments except when the embryo was protected by being turned away from the radium. The retardative effect relative to the duration of exposure increased with the lengthening of the exposure, then decreased, and finally became constant with a slow increase of retardation. Very short irradiation in the case of mustard and millet seed left doubt as to whether acceleration occurred or not. By comparing the retardation of mustard and millet when the embryo was turned toward and away from the radium it was found that this part of the seed was especially sensitive to the electrons.

**Dry matter, nitrogen, and mineral content of trees during the vegetative period,** E. RAMANN and H. BAUER (*Jahrb. Wiss. Bot. [Pringsheim]*, 50 (1911), No. 1, pp. 67-83; *abs. in Bot. Centbl.*, 119 (1912), No. 20, pp. 491, 492).—Investigations with young trees of various common species led to the following conclusions:

The new growth of foliage trees in the spring takes place chiefly by the expenditure of materials previously stored, which are often broken down and utilized in large quantities in such trees. Conifers utilize in addition newly assimilated materials, different species drawing on the soil supply during different periods. For example, nitrogen assimilation by fir trees takes place most actively during the period from September until about May 15; by pine trees from that time until July 15; and by Scotch fir and larch trees thereafter until September 15. The relations of the phosphorus compounds are about the same. These facts suggest the cultivation of a mixed stand for the best utilization of the abundant materials in a rich soil. See also previous notes (E. S. R., 25, p. 27; 27, p. 229).

**The mineral content of tree foliage as affected by day and night,** E. RAMANN (*Jahrb. Wiss. Bot. [Pringsheim]*, 50 (1911), No. 1, pp. 84-91; *abs. in Bot. Centbl.*, 119 (1912), No. 20, p. 491).—Analyses made, in pursuance of previous studies (see above), of leaves of beech, oak, hazel, plane tree, maple, etc., indicate that while other minerals do not show any considerable difference for day and night, the calcium content (as computed on the basis of the dry substance) increases at night and decreases by day. A possible connection is suggested between the relative quantity of this mineral present and the trans-

portation or assimilation products, which is said to be more active during the hours of daylight.

Changes in the osmotic pressure of the sap of the leaves of various plants, H. H. DIXON and W. R. G. ATKINS (*Sci. Proc. Roy. Dublin Soc., n. ser., 12* (1912), Nos. 16, pp. 219-222; 18, pp. 229-238, figs. 2; 19, pp. 239-246, fig. 1).—Investigations have been made on the changes in the osmotic pressure of the sap of the leaves, the method employed being that described elsewhere (E. S. R., 23, p. 526).

Experiments with *Syringa vulgaris* were carried on to trace the changes in the osmotic pressure during the unfolding of the buds and the maturing of the leaves. It was found that the osmotic pressure of the sap of the buds rose from February to March, and this is attributed to the transportation of dissolved substances into the buds and to the solution of previously undissolved bodies in them. In April the rapid increase in size of the leaves was associated with a dilution of the sap, indicating that during this period the absorption of water predominated over the accumulation of dissolved substances. From that time on, as the leaves grew and matured, the pressure continued to rise until June, when the observations were brought to a close. Previous observations, however, indicate that the pressure continues to rise in the leaves during the summer. After the final rise of osmotic pressure in the late summer a diminution is registered in the sap from the leaves just about to fall. This is attributed to the transportation of materials from the leaves.

In the second and third papers the materials selected for investigation were the leaves of evergreen plants. In *Ilex aquifolium* there was not only a difference observable between the mature and immature leaves in their osmotic pressure, but also between mature leaves of various ages.

With *Hedera helix* the effect of direct sunlight on osmotic pressure was investigated, and with this plant it was also found that the age of the leaves had a marked influence on the concentration of the cell sap. Leaves of the ivy which were grown in a southern aspect had a consistently higher cryoscopic value than those of leaves grown in a northern aspect. This confirms other observations which showed that the depression of freezing point of the sap of the aerial portions of plants was greater in plants grown in a sunny position than in those grown in more shaded situations. In *Hedera* as in *Ilex* the depressions in the curve seemed to correspond to periods of elongation of the shoots and the formation of new leaves, and it was found impossible to correlate the form of the curves closely with external conditions. The effect of photosynthesis on variation in osmotic pressure was investigated, and the results indicate that photosynthesis is active in raising the concentration.

The formation of mechanical tissue as influenced by tension and contact, W. D. BRUSH (*Bot. Gaz., 53* (1912), No. 6, pp. 453-477, figs. 3).—Studies are reported on the formation of mechanical tissue in the tendrils of *Passiflora caerulea* as influenced by tension and contact. The experiments were conducted in the greenhouse under control conditions and the results are given in detail.

It was found that the tendrils which function to support the plant possess a greater breaking strength than those which have grasped no support. The cause of this greatly increased strength is attributed to a combination of the two factors contact and tension. Comparing the values of these two factors, the author concludes that contact plays the more important part, though the strength of the tendril may be still more increased by the factor of tension. The author claims that tension may also act as a stimulus and thereby result in the production of stronger tissues in the plant. It is thought probable that this increased growth is due to increased hydrostatic pressure.

A bibliography is appended.

The admission of anilin colors into living plant cells, E. KÜSTER (*Jahrb. Wiss. Bot. [Pringsheim]*, 50 (1911), No. 3, pp. 261-288; *abs. in Bot. Centbl.*, 119 (1912), No. 20, pp. 488, 489; *Ztschr. Bot.*, 4 (1912), No. 6, p. 450).—The author reports as the results of his experiments that various anilin solutions are taken up by living parenchyma cells near the vascular bundles and stored and strongly held by such cells, this being conspicuously true in case of epidermal cells of leaves and flowers. The cells in question exhibited a selective power when provided with different colored solutions. The coloring matter once admitted is not washed out if immersed for some time in standing or running water. Thus, several acid coloring matters have now a claim to be considered as vitally colorative, a character heretofore generally considered to be limited to basic colors. Only a very few colloidal substances are found to possess this ability. Transpiration favors greatly the entrance of coloring matters into the cells.

The significance of respiration pigments in the oxidation processes of plants, W. PALLADIN (*Ztschr. Gärungsphysiol.*, 1 (1912), No. 2, pp. 91-105).—Continuing previous work (E. S. R., 27, p. 426), the author gives the final results of his studies on the relation of respiration pigments to oxidation processes, in substance as follows:

The rôle of these pigments in the oxidation processes consists in the withdrawal of hydrogen from the oxidizing substance. The oxidases appears as ferments, building both water and pigment. During respiration the entire hydrogen of the glucose, which is anaerobically broken up, is oxidized to water. The oxidation of glucose by the aid of a respiratory pigment occurs with the participation of water. Such oxidation occurs partly by use of the oxygen in the glucose, partly by employment of that in the water assimilated, water being both produced and assimilated during this process. The respiration pigments are held to be necessary to the intracellular respiration and to the oxidation of the hydrogen. The chemical reactions held to support these statements are given in some detail.

Distribution of pigment in the seed coat of the cowpea, A. MANN (*Abs. in Science, n. ser.*, 35 (1912), No. 913, p. 1004).—A study of the seed coat of the cowpea showed that it is composed of 3 principal layers of cells, an outer palisade layer, a heavy-walled layer of empty cells below this, and a layer of considerably compressed cells with a long axis parallel to the surface of the cowpea.

It was found that the colorations in the cowpea are the result of pigments deposited in 2 of these layers. In all colored cowpeas there is in the lowest layer a basal color or practically uniform tint, which is a melanin compound of an orange-yellow tint, grading into lemon yellow and pale buff. All the other colors are obtained by superposing upon this basal color layer various pigments, and these are uniformly deposited in the palisade cells. The 3 colors found in the palisade cells are black or blue-black, sometimes purple, which is an anthocyanin, a yellow or a brown pigment, and an intensely black pigment, the last 2 being melanin compounds. By various arrangements of these superposed tints, or by the absence of any pigments in these cells, the various schemes of coloration in the cowpea are obtained.

In the case of cowpeas having white or colorless seed coats, the result, it is stated, is obtained by the suppression of all pigments, both in the basal color layer and in the palisade color layer.

A wild cowpea secured from Africa showed the same elements of color as well as the schemes of coloration.

The distribution of oxidases in plants and their rôle in the formation of pigments, F. KEEBLE and E. F. ARMSTRONG (*Proc. Roy. Soc. [London]*, Ser. B,

85 (1912), No. B 578, pp. 214-218).—Studies were made of the distribution of oxidases in connection with the formation of pigments in the Chinese primrose (*Primula sinensis*).

The distribution of pigment in the flower was found to coincide with that of peroxidases, two of which were found in the primrose, one occurring in the epidermis and in some cases in the layers subjacent to the epidermis, while the other was localized in layers of cells neighboring the woody tissues of the vascular bundles. The epidermal and bundle peroxidases were found to differ from one another both in their distribution and in their color reactions. Certain varieties of the Chinese primrose give under certain circumstances a direct oxidase reaction. The bundle peroxidase of the petals of the flower is located in the cells of the bundle sheath which surrounds the veins.

White flowers which are known to be dominant whites are said to fail to give the epidermal peroxidase reaction, but in such flowers a faint bundle peroxidase reaction may occur. Both epidermal and bundle peroxidases are, however, present in dominant white flowers, the white primulas containing a substance which inhibits but does not destroy the pigment-producing peroxidase.

Observations made on the epidermal and bundle peroxidases are believed to throw light on the significance of sporting in cultivated flowers, the authors being inclined to regard flaking as the effect of the bundle peroxidase on the chromogen-containing cells neighboring on the bundle sheath. The white color is attributed to an inhibitor associated with and nullifying the epidermal peroxidase. The marked localization of pigmentation effected by bundle peroxidase appears to be due to anatomical causes, such as the degree of development of the cells and the nearness of the veins to one another.

The existence of two localized peroxidases which may induce pigmentation and may reinforce one another along certain tracts of tissue is held to provide material facts for the explanation of color range and color pattern in flowers.

The occurrence of urease in higher plants, G. ZEMPLÉN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 79 (1912), No. 3, pp. 229-234; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 597, II, p. 674).—In a series of investigations to ascertain the presence and proportion of urease in certain agricultural plants, the author found it in a large number of the Papilionaceae, different species of which contain this enzyme in widely varying percentages, while in the Gramineae it was present, if at all, in quantities scarcely demonstrable in most cases. Tabulated details are given and an early discussion is promised.

The action of bisulphid of carbon on the germination of seeds, B. FINZI (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 11-12, pp. 843-848).—A preliminary note by the author on his experiments shows that exposure to carbon bisulphid vapor during periods varying from 30 minutes to 48 hours accelerated the germination of seeds of *Egilops cylindrica*, *Bromus erectus*, *Trigonella fœnum græcum*, *Panicum miliaceum*, *Canna cupheana*, and *C. orientalis*. The seeds of 8 other species either showed little or no acceleration or appeared to be retarded.

Nutritive changes in sprouting pumpkin seeds, F. T. PERITURIN (*Izv. Moskor. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscow)*, 18 (1912), No. 2, pp. 228-256).—The pumpkin seeds experimented upon were divided into 4 lots and sprouted in water and in solutions of ammonium chlorid, ammonium chlorid with calcium carbonate, and ammonium chlorid with calcium sulphate. After 10 days the seedlings were analyzed and the fat and nitrogen contents ascertained. The results are given in tabular form. It appears therefrom that etiolated seedlings take up ammonia not as such but as asparagin, the larger results being obtained when the calcium salts were employed with ammonium salt in the nutritive solutions.

The formation of asparagin in sprouting vetches, G. I. RITMAN (*Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscow)*, 18 (1912), No. 2, pp. 212-220).—From studies of young seedlings of *Vicia sativa*, nourished with ammonia and nitrates, the author concludes that almost all the nitrogen assimilated by the roots in darkness goes into the formation of asparagin.

Protein formation by sterile cultures of higher plants in darkness, I. SHULOV (*Zhur. Opytu. Agron. (Russ. Jour. Expt. Landw.)*, 13 (1912), No. 2, 207-210).—Investigations carried out with sterile cultures of maize in darkness, supplied with a prepared carbohydrate (saccharose), are said to have shown the following results: Assimilation of the nitrogen-free organic material, the depressing effect of ammonium sulphate on plant development, the decrease of such unfavorable influence by employment of ammonium nitrate, a considerable increase of proteins, and confirmation of the practicability and reliability of the methods here employed.

The utilization of ammoniacal nitrogen by corn plantlets, S. I. KALINKIN (*Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscow)*, 18 (1912), No. 1, pp. 189-192).—The author experimented with 4 different lots of young maize plants kept in darkness for 10 days and supplied, respectively, with (1) water, (2) a 0.975 per cent solution of ammonium chlorid, (3) the same percentage of the chlorid plus calcium carbonate, and (4) of the chlorid with calcium sulphate.

The results showed that the nitrogen of the ammoniacal salt is utilized by the plant in the construction of protein, either directly or through the formation of asparagin. The results, in general, agree with those obtained by Prianishnikov and Shulov with peas (*E. S. R.*, 24, p. 629), Godlewski with grains (*E. S. R.*, 26, p. 625), and of Ritman with vetches and Periturin with pumpkin seeds, noted above.

Further experiments on the utilization of ammonium salts by green plants, E. PANTANELLI and G. SEVERINI (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 11-12, pp. 873-908).—Continuing previous work (*E. S. R.*, 25, p. 223), the authors find that ammoniacal nitrogen has a potential nutritive value for plants superior to that of nitrates, but the full expression of that higher value is conditioned upon (1) slow absorption of the ammonium cation by the roots, (2) about equal absorption of the corresponding anion, and (3) the possession of a nutritive value by the anion itself.

The presence of nitrifying bacteria in ordinary sand cultures, I. SHULOV (*Zhur. Opytu. Agron. (Russ. Jour. Expt. Landw.)*, 13 (1912), No. 2, pp. 211-215).—By introducing into the substratum for nitrifying bacteria sand from ordinary cultures, the author was able to show that these bacteria may be present in such cultures and that the process of nitrification may occur therein. Notable losses of ammonia gas were observed by this investigator, as previously by H. Astafjew, and attributed to the action of magnesium carbonate on ammonium sulphate.

On the presence of glutamic acid in the tomato, N. MONTE (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 11-12, pp. 813-823).—The author claims to have demonstrated the presence of this acid in the sap of tomatoes, but has been unable to determine its origin.

On anthocyanin-forming bodies, J. POLITIS (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 20 (1911), I, No. 11, pp. 828-834; *abs. in Bot. Centbl.*, 119 (1912), No. 21, p. 524).—After a brief discussion of the mechanism of anthocyanin formation, the author gives an account of his investigations with flowers of *Billbergia nutans*, *Iris fimbriata*, *Lalia anceps*, *Aquilegia glandulosa*, *Erica carnea*, *Nepeta glechoma*, *Clerodendron balfourii*, *Weigela japonica*, *W. rosca*, and on fruits of *Convallaria japonica*.

It is concluded that anthocyanin is not formed from substances in the cell sap, but is the product of special organs termed cyanoplastids. These originate from the protoplasm as a new product, being made up largely of tannin-like substance inclosed in an envelope of unknown chemical composition, both envelope and contents, however, being able to become sources of anthocyanin. Certain external agencies seem able to hinder or prevent a transformation of the cyanoplastid material into anthocyanin, this body remaining colorless. Each cyanoplastid seems to pass through a determinate cycle of development. When degeneration begins, the pigment formed therein is given up to the cell sap. Different kinds of anthocyanin are found, giving various colors, which do not depend upon the acidity of the cell sap to color a given pigment differently.

On the presence of free hydrocyanic acid in plants, II, C. RAVENNA and V. BABINI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 21 (1912), I, No. 8, pp. 540-544).—By methods previously described (E. S. R., 24, p. 229), the authors have made a study of the leaves of cherry laurel, peach, sorghum, flax, and medlar, and have found that free hydrocyanic acid occurs in appreciable quantity in all of them.

The selective power of plants for dextrose and levulose, L. LINDET (*Ann. Inst. Nat. Agron.*, 2. ser., 10 (1911), No. 1, pp. 49-63; *abs. in Bot. Centbl.*, 119 (1912), No. 20, pp. 489, 490).—This article has been previously noted from other sources (E. S. R., 25, p. 522).

Potassium in relation to carbohydrate formation and decomposition, J. STOKLASA (*Ztschr. Landw. Versuchsw. Österr.*, 15 (1912), No. 6, pp. 711-736).—In pursuance of previous studies, noted elsewhere (E. S. R., 25, p. 522; 26, p. 225), on the physiological influences of certain metals, the author experimented with the action of potassium on cells of several plants. He concluded that potassium is generally indispensable to the building of carbohydrates, as well as for their physiological combustion, also in the metabolic processes occurring both in cells which lack and those which possess chlorophyll.

The action of sulphurous acid on pollen, V. SABACHNIKOFF (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 5, pp. 191-193; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 4, pp. 1049, 1050).—The author reports that in an atmosphere saturated with sulphurous acid, pollen of the following plants was killed by an exposure of from 3 to 5 minutes: *Helleborus viridis*, *H. orientalis*, *Hepatica triloba* (*Aucumne hepatica*), *Galanthus nivalis*, *Primula officinalis*, *Vinca minor*, *V. major*, *Convallaria majalis*, *Narcissus peticus*, *Caltha palustris*, *Cytisus laburnum*, *Viola tricolor*, *Orchis maculata*, *Billbergia*, *Eranthis*, and *Crocus*.

Very small proportions of sulphurous acid (between 1:1,000 and 1:30,000 with exposures from 3 to 48 hours) do not as a rule kill the pollen or destroy its germinating power, but the pollen tube grows abnormally, usually remaining short, and taking an irregular form. This is said to have been noted in the case of *A. hepatica*, *Billbergia*, *H. orientalis*, *Vinca minor*, *Viola tricolor*, *P. officinalis*, *Lilium candidum*, *Petunia*, and *Pisum*. The germinating property of pollen remained unimpaired after exposure of from 1 to 48 hours to sulphurous acid with a concentration of 1:48,000, but this property was usually destroyed by a 3-hours' exposure to the concentration of 1:13,000, which conditions of exposure may be considered as about the limits of safety for these pollens.

Injury to plants by vapors and dust from tarred roads, C. L. GATIN (*Ztschr. Pflanzenkrankh.*, 22 (1912), No. 4, pp. 193-204).—This is a further account of the author's investigations (E. S. R., 27, p. 333), stating that both laboratory and garden studies support the conclusions that coal tar and its products carried by air and dust to foliage are injurious to the plants; that such

injury does not always become apparent at first, in some cases not within 2 years; and that sunlight favors the injurious action of the tar products in certain cases.

A bibliography is appended.

**A study on the influence of starvation of the ascendants upon the characteristics of the descendants.** I. J. A. HARRIS (*Amer. Nat.*, 46 (1912), No. 546, pp. 313-343, *dgms.* 7).—The author presents his first report on a study of 5 series of garden beans, giving a statement of the problem and a description of the methods, the work having been carried on for some time and involving about 21,000 individuals.

The purpose of the investigation was to ascertain whether the artificial de-paupORIZATION of the ancestors has any influence upon the characters of the offspring. Beans were planted in ordinary fertile and sterile soils or good and poor agricultural land, and the influence of from one to three generations was studied. Thus far, it is stated, hardly any difference can be detected by the eye in the field, but the statistical constants seem to show a slight influence of the treatment of the ancestors in the form of a slight decrease in the number of pods per plant.

The data are as yet insufficient to justify any discussion of the question of the cumulative influence of the starvation conditions or of the mechanism through which the characters of the plants are modified.

**Chromosome numbers in Triticum and Ægilops.** W. BALLY (*Ber. Deut. Bot. Gesell.*, 30 (1912), No. 4, pp. 163-172, *pl.* 1).—This is a cytological contribution to the study of relation among the wheats, based upon a study of the chromosome numbers. It is stated that (1) *Triticum dicoccoides* has 8 simple chromosomes, in this respect resembling *T. vulgare* and *Secale cereale*, and (2) *Ægilops ovata*, which is able to hybridize with species of *Triticum*, has 16 simple chromosomes.

A bibliography is appended.

**Soil moisture in the cottonwood dune association of Lake Michigan.** G. D. FULLER (*Bot. Gaz.*, 53 (1912), No. 6, pp. 512-514, *fig.* 1).—The author records data regarding the range of soil moisture in the cottonwood dune association upon the shores of Lake Michigan. This area is considered an open association of a single tree species, together with a scanty undergrowth of shrubs and grasses, developing upon more or less rapidly moving dunes, possessing a high rate of evaporation and exhibiting many strongly xerophytic characters. The almost complete absence of herbaceous undergrowth and the expanse of bare sand give it a desert-like aspect, but below the superficial layer of sand an abundant and unfailling water supply has been found.

The wilting coefficient of the dune soil was determined by the method of Briggs and Shantz (*E. S. R.*, 26, p. 628) to be 0.75 per cent. Throughout the most arid portion of the season the surplus of growth water was found to average 2.2 per cent, showing that, considered upon the basis of its soil moisture, the association is decidedly mesophytic. The causes of the xerophytic character of the vegetation are believed to be the high evaporating power of the air and the instability of the substratum.

From the data obtained the author believes that the determination of soil moisture, related to plant growth through the wilting coefficients of the soil, will afford an efficient means of making quantitative studies of the water supplies of the subterranean parts of plant associations, and enable students of ecology to analyze more closely the effects of various factors influencing the production of any particular plant association.

**A comparison of the rates of evaporation in certain associations in central Illinois.** H. A. GLEASON and F. C. GATES (*Bot. Gaz.*, 53 (1912), No. 6, pp. 478-

491, figs. 6).—An account is given of a series of measurements of the relative rates of evaporation in certain plant associations made during June and July, 1910. The authors used porous clay atmometers for determining the differences in evaporation, and it was found that the differences in the various associations are due chiefly to the nature of the vegetation, which by its size and density controls the evaporation beneath it. It is claimed that successions between associations are not caused by any conditions of evaporation, and that the more primitive associations have the higher rates of evaporation, while those most nearly like the climax type have the lowest rates. This is held to be true not only for forest associations but also for prairie associations, which are correlated with an arid climate and consequently high climatic evaporation.

Seeds and plants imported during the period from July 1 to September 30, 1911—Inventory No. 28 (*U. S. Dept. Agr., Bur. Plant Indus., Bul. 248, pp. 71*).—This gives a list with descriptive notes of seeds and plants imported during the period mentioned, more than 500 items being included. A large portion of the material was obtained by Mr. F. N. Meyer in Chinese Turkestan, and the balance from miscellaneous sources.

### FIELD CROPS.

Results obtained in 1911 on the Dominion experimental farms from trial plats of grain, fodder corn, field roots, and potatoes, C. E. SAUNDERS (*Canada Cent. Expt. Farm Bul. 71, 1911, pp. 74*).—Results of a large number of experiments conducted at the experimental farms during the season of 1911 with important varieties of wheat, oats, barley, peas, corn, turnips, mangels, carrots, sugar beets, and potatoes are presented. The results show marked differences in earliness and in the relative productiveness of varieties even when grown under similar conditions. Lists of recommended varieties of the different crops suitable for the different provinces or districts are given. The publication of data as to the average yields obtained during a series of years, as noted in previous bulletins (*E. S. R., 24, p. 435*), has been discontinued.

Second report on experiments, botanical experiment station, Salisbury, 1910–11, J. H. HAMPTON (*Rhodesia Agr. Jour., 8 (1911), No. 6, pp. 853–862; 9 (1911), No. 1, pp. 16–23, pls. 4*).—Moderately satisfactory results were obtained with dry-land alfalfa. Egyptian clover, velvet beans, cowpeas, lupines, ground nuts, sweet potatoes, wheat, oats, Teff grass (*Eragrostis abyssinica*), teosinte, sugar cane, and various millets were tested for summer forage. Velvet beans yielded 3,680 lbs. of cured hay per acre and proved more satisfactory than cowpeas. Only the Black-eyed Susan and Iron cowpeas gave satisfactory results. American peanuts and sweet potatoes proved superior to the native varieties. Other crops discussed are flax, mangels, sugar beets, swedes, kohlrabi, carrots, rape, beans, and peas.

Annual report of the experimental work of the Bankipore Agricultural Station, 1910–11 (*Ann. Rpt. Bankipore Agr. Sta. [Bengal], 1910–11, pp. 10*).—Two rice seedlings per hole gave greater yields of grain and straw than plantings of 1, 4, or 8 seedlings per hole. Green manuring with sann hemp was followed by somewhat greater yields of rice and straw than green manuring with dhaincha, and both by much greater yields than from the unmanured plats. Other work reported includes variety and fertilizer tests with rice and a fertilizer test with sugar cane.

Annual report of the Cuttack Experimental Farm, 1910–11, A. C. DOBBS (*Ann. Rpt. Cuttack Agr. Sta. [Bengal], 1910–11, pp. 11*).—Transplanting rice at the rate of 1 seedling per hole gave a greater 5 years' average yield than transplanting at the rate of 2, 3, or 4 seedlings. Other work reported includes

variety, fertilizer, rate of seeding, and irrigation tests with rice, a comparison of broadcasting and transplanting rice, and a fertilizer test with sugar cane.

Annual report of the agricultural stations in Eastern Bengal and Assam for the year ending June 30, 1911 (*Ann. Rpt. Agr. Stas. East. Bengal and Assam, 1911, pp. II+99, pls. 3*).—Previous work has already been noted (E. S. R., 26, p. 233).

Work with rice, sugar cane, cotton, soy beans, and fodder crops is reported for the Dacca station, with tobacco, oats, mustard, wheat, potatoes, peanuts, green manure, and fodder crops at the Burirhat station, with rice and sugar cane at the Rajshahi station, with sugar cane, peanuts, potatoes, and the application of lime at the Jorhat station, with fruit and garden crops at the Shillong fruit station, and with potatoes, oats, flax, soy beans, ensilage, and fodder at the Upper Shillong station. A brief progress report of work at the Wahjain station is also given.

At the Jorhat station the Striped Mauritius sugar cane stood first in total yield of sugar, followed by B 376 and B 147. These 3 varieties were also superior to the others in quality of juice. At the Upper Shillong station it proved better to plant whole potatoes than to cut them in case of what the author terms summer seed, but the cut sets produced the highest yields in case of winter seed.

Annual report of the demonstration farm, St. Andrew's Colonial Homes, Kalimpong, for the year 1910-11, P. W. GOODWIN (*Ann. Rpt. Kalimpong Demon. Farm, Bengal, 1910-11, pp. II+40*).—A report of fertilizer, variety, and other tests of corn, rice, jute, buckwheat, barley, spelt, oats, soy beans, and other crops.

Field crops at the Taganrog Experiment Field during 1899-1908, N. OLEIN (*Khoz'istvo, 1911, No. 6-7; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. (Landw.)), 12 (1911), No. 4, pp. 572, 573*).—This is an account of the first 10 years' work on these fields. Early green fallow appeared preferable to all other kinds. Fall plowing 5½ in. deep gave better results than either more shallow or deeper plowing, but in the spring 3½ in. appeared to be the best depth.

Moor culture handbook, W. BERSCH (*Handbuch der Moorkultur, Vienna and Leipsic, 1909, pp. XII+288, pls. 8, figs. 41*).—This manual of information is divided into 10 chapters, dealing with the historical, scientific, soil, cultural, forestry, weed control, and economic phases of the subject.

Manuring of meadow land (*Rpt. Dir. Agr. Ed., Monmouthshire Ed. Com., 1911, Oct. 18; abs. in Jour. Bd. Agr. [London], 18 (1912), No. 11, p. 941*).—This is a report of fertilizer tests on 3 different soils since 1909.

Manuring of poor hill pastures (*Rpt. Agr. Instr. Com. Somerset. County Council, 1911; abs. in Jour. Bd. Agr. [London], 18 (1912), No. 11, p. 941*).—This is a report of tests of basic slag, superphosphate, lime, and kainit at 4 points in Somerset. Slag and superphosphate apparently produced a marked improvement, but little or no result followed the use of ground lime or of kainit.

The grain crops, J. F. HOFFMANN (*Das Getreidekorn, Berlin, 1912, vol. 1, pp. VII+249, figs. 77*).—In the 5 parts into which this work is divided, the author considers the general and botanical characters of the grain crops, with special reference to their production and diseases. Fungus and insect enemies and the insects injurious to stored grains are also treated. In the chapter dealing with the botanical and cultural phases of the subject, separate discussions deal with rye, wheat, barley, oats, rice, corn, beans, and buckwheat.

Rate of sowing summer cereals, A. DANILENKO (*Iugo Vost. Khoz. 1910, No. 42; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 12 (1911), No. 4, pp. 581, 582*).—This article reports the results of tests of rates of sowing swedes, oats, and barley in rows at the Don Experiment Field.

**Grain sowing in wide rows, A. DANILENKO** (*Jugo Vost. Khoz.* 1910, No. 42; *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landic.)*, 12 (1911), No. 4, p. 581).—In 1910 at the Don Experiment Field the usual continuous sowing in rows was compared with sowing in single and double rows 14 in. or less apart with wheat, oats, barley, and millet. Sowing in wide rows apparently decreased the yield of wheat, but increased the yields of oats, millet, and barley, except in the case of the double rows, to an extent sufficient to make sowing in wide rows profitable.

**The composition of Cape barley, C. F. JURITZ** (*Agr. Jour. Union So. Africa*, 3 (1912), No. 4, pp. 516-529).—Tables report analyses of 47 samples of barley, and the location, character, cultural treatment, and fertilization of the soil upon which each was grown.

**The dissemination of brewing barley in Germany, II. SCHULZE** (*Wechschr. Brou.*, 28 (1911), Nos. 32, pp. 350-356; 33, pp. 367-371; 34, pp. 382-385; 35, pp. 397-400, fig. 1).—This article presents the information obtained in an investigation of the present geographical distribution of brewing barley varieties in Germany, and suggests varieties that are likely to come into general use in certain sections.

**Bogoroditsch Experiment Field, I. A. PULMAN** (*Ezheg. Dept. Zoml. [Russia]*, 1909, pp. 51-77, pls. 10; *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landic.)*, 12 (1911), No. 4, pp. 582-584).—Meteorological data and descriptions of the soils of the Bogoroditsch Experiment Field in Staros-Kalsk County in the Kursk government accompany a statement of the results of 8 years' experimental work dealing largely with buckwheat. The observations reported deal with the effect of rate of planting, soil moisture, and the amount and distribution of sunshine during the season on the structure and development of the buckwheat plant. Work is also being done on the production of a 4-faced strain or variety which is more resistant to early spring frosts and produces heavier seeds.

**The manuring of carrots, E. E. STOKES** (*Midland Agr. and Dairy Col. B. J.* 4, 1911-12, pp. 39-44).—The author concludes that the soil usually planted to carrots should receive salt, especially during a hot, dry season, that potash in some form is absolutely necessary, and that phosphates stand next in order of importance.

**Manurial experiments on maize, H. J. VIBOND** (*Agr. Jour. Union So. Africa*, 2 (1911), No. 5, pp. 618-623).—In a test of 13 applications of lime, phosphate, slag, bone meal, sulphate of potash, and nitrate of soda, singly or in various mixtures and amounts, the highest corn yields followed the use of 400 lbs. of bone meal and 400 lbs. of basic slag. Analyses of 20 Transvaal soils are given.

**Corn growing in the East, T. F. HUNT** (*Pennsylvania Sta. Bul.* 116, pp. 16, figs. 5).—After a study of the acreage devoted to each of a number of crops in the North Atlantic States, the author concludes "that the composite eastern farmer has a 7 years' rotation in which an intertilled crop, a spring grain, and a winter grain each occupy 1 year, while hay occupies 4 years." Based on results secured by the station and previously noted (*E. S. R.*, 3, p. 713; 26, p. 167), the following rotations are suggested: (1) Corn, wheat, clover and timothy; (2) corn, oats, wheat, clover and timothy; (3) corn, oats, wheat, clover and timothy, timothy; and (4) 2 years in corn, one each in oats, wheat, and clover and timothy, and 2 in timothy.

Portions of letters from experiment-station workers in the North Atlantic States are reprinted and photographs illustrate sample ears submitted in response to a request for samples of varieties worthy of special mention. In nearly every instance 2 types were recommended, an 8-rowed flint, and a

medium-sized dent to which the name Pride of the North was usually given. The only exceptions to this rule were the southern portions of New Jersey and Pennsylvania, and the more northern portions of the New England States.

**How to grow one hundred bushels of corn per acre on worn soils,** W. C. SMITH (*Cincinnati, 1912, 2. ed., rev. and enl., pp. 188, pls. 24*).—This handbook of information for corn growers is written with special reference to the restoration of worn-out soil for corn production.

**Observations on certain extra Indian Asiatic cottons,** H. M. LEAKE and R. PERSHAD (*Mem. Dept. Agr. India, Bot. Ser., 4 (1912), No. 5, pp. 93-114, pls. 7*).—Botanical and other information on the cottons of Persia, China, and Siam.

**The branching habits of Egyptian cotton,** A. McLACHLAN (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 249, pp. 28, pls. 3, fig. 1*).—This bulletin presents results of a study of the branching habits of Egyptian cotton conducted for the purpose of developing a system of cultivation adapted to the irrigated districts of southern California and Arizona. By means of especially devised diagrams for recording the branching habits of the plant, the location of branches, the development of fruiting branches, and the stature of plants are illustrated.

It is pointed out that the Egyptian cotton plant bears 2 kinds of branches, long vegetative branches on the lower part of the stem bearing no flower buds directly, and above these shorter fruiting branches, which bear flower buds. The vegetative branches usually approximate the length of the main stem, bear no flower buds except as they produce secondary fruiting branches, and, like the axis, bear fruiting branches and may bear vegetative branches. The fruiting branches, on the other hand, are about only one-third as long as the vegetative branches, bear a flower bud at each node opposite the leaf, and rarely bear fruiting branches or vegetative branches. It is stated that from 6 to 8 large vegetative branches are usually produced from the first 10 nodes of the axis, and that at the next 2 or 3 nodes the buds frequently remain dormant or are abortive, while above these a fruiting branch is produced at each node.

The length and number of vegetative branches largely determine the stature of the plant, and their control is necessary because of the desirability of small plants in cultivating and harvesting. As a means of restricting the development of branches early planting is advised.

Abortion of early fruiting branches on both axis and large limbs was common in a greater or less degree to all stocks grown from imported seed. It has been found that the Arizona acclimatized plants frequently abort their lowest fruiting branches. Some of the selected acclimatized types of Egyptian cotton, originated in the United States, bear fruiting branches at lower nodes on the stem than the imported stocks. Of the 6 Egyptian varieties grown in Arizona in 1909 from imported seed, Nubari most nearly resembled the acclimatized stocks in putting out fruiting branches at comparatively low nodes. Topping young plants resulted in stimulating the growth of buds in the axils of cotyledons. Branches just below the point where the plant was topped make an excessive vegetative growth and tend to assume an upright position in place of the severed axis. Egyptian cotton plants grown on soil containing considerable alkali restrict the development of limbs and reject their early fruiting branches.

**Cotton improvement under weevil conditions,** O. F. COOK (*U. S. Dept. Agr., Farmers' Bul. 501, pp. 22*).—This publication discusses various factors in their bearing upon the profitable and progressive culture of cotton under weevil conditions, special attention being given to earliness in the variety and cultural methods. It is pointed out that "the general object of all measures of controlling or resisting the boll weevil is to shorten the period . . . between the formation of flower buds and the growth of the bolls beyond the danger of weevil

injury. . . . While earliness becomes a more important factor than before there is nothing to indicate that superior varieties are likely to be excluded from cultivation in any section that continues to grow cotton in the presence of weevils. . . . Many advantages can be gained if the cotton growers of each community would unite in the choice of a variety and the date of planting and would follow the same methods of cultivation, selection, ginning, and marketing the crop."

**The influence of Russian weather conditions in 1902 on oats,** K. MIKHAILOVSKĪ (*Trudy Sel'sk. Khoz. Mcl.*, 1910, No. 6, pp. 1-20; *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 12 (1911), No. 6, pp. 925, 926).—After drought and excessive heat, 35 per cent of the oat heads were imperfectly developed or contained no seed. When stalks appeared 11.7 per cent of them were destroyed, and lightness of grain at harvest time reduced the yield by from 13 to 20 per cent. The total loss arising from meteorological conditions is estimated at 59.7 per cent of the crop. The data obtained are more fully stated in tables and charts.

**Wild oats and false wild oats: Their nature and distinctive characters,** N. CRIDDLE (*Canada Dept. Agr., Seed Branch Bul.* 8-7, 1912, pp. 11, pls. 4).—Examples of the Banner, Newmarket of Abundance, Old Island Black, and Storm King types of false wild oats (also called sports, white wild oats, and albino wild oats) have been grown for from 2 to 7 years without change in appearance. A black oat of unknown name also grew true to type for 2 years. The author does not regard false wild oats as dangerous or think it likely that they result from crosses of wild and cultivated species.

**Annual report of the Dumraon Agricultural Experiment Station, 1910-11,** A. C. DOBBS (*Ann. Rpt. Dumraon Expt. Sta. [Bengal]*, 1910-11, pp. 5).—This is a report of fertilizer, variety, and drainage tests of rice.

**The "Ráb" system of rice cultivation in western India,** H. H. MANN, N. V. JOSHI, and N. V. KANITKAR (*Mem. Dept. Agr. India, Chem. Ser.*, 2 (1912), No. 3, pp. 171-193).—A brief account of earlier experiments on the value of the "Ráb" system (*E. S. R.*, 23, p. 129) is followed by a full discussion and numerous tables presenting the data obtained in the authors' experiments, from which the following conclusions are drawn:

The benefits from this system vary widely but "normally the weight of the seedlings obtained is from one and a half times to twice as great as without the treatment." Nearly 60 per cent of this increase results from heating, the remainder being due to the ash and other materials added. During ordinary burning with cow dung the temperature does not rise above 110° C. at a depth of  $\frac{1}{2}$  in. and 85° at a depth of 1 in., and the heating process lasts from 1½ to 2 hours or less.

Only very slight results were obtained by heating the soil to 75°. At higher temperatures the fertility was greatly increased, reaching a maximum at about 125°. The maximum effect resulted from heating immediately before the sowing of the crop. A little less effect resulted from heating 6 weeks before sowing, while comparatively little effect resulted from heating 3 months before sowing.

The supply of assimilable mineral plant food and of soluble organic matter in the soil was considerably increased by heating, but little effect was produced when growing rice plants were treated with extracts of such heated soils. The speed of germination was not beneficially affected but was apparently slightly retarded at times. This did not appear to be due to the production of a deleterious substance.

Heating materially changed the physical condition of the soil by bringing a large part of the viscous, sticky clay substance into such condition that it

would not remain in suspension in water. This effect was temporary, disappearing after 3 months, and the mere keeping of air-dry soil for 6 weeks materially reduced it. This power to precipitate soil is shared by oil cake (safflower cake) but not by any other cakes tested. This change in the physical condition of the soil is only a secondary cause of the beneficial effect of the "Ráb" process.

The heating destroyed a large proportion of the active aerobic life of the soil, but even when the soil was kept in an air-dry condition this aerobic activity became far greater in 6 weeks than in the unheated sample, though this difference disappeared on further keeping of the soil. Soil fertility is not considered dependent on the presence of aerobic soil organisms during plant growth, but on the contrary "the fertility of a heated soil is greatest when the aerobic organisms present are fewest."

The author suggests as a more economical method of obtaining the benefits of this method that soil be burnt in heaps, as this would require less fuel and work.

**The mutual relations of weight and sugar content in *Beta vulgaris saccharifera*,** K. ANDRLÍK, V. BARTOŠ, and J. URBAN (*Ztschr. Zuckerindus. Böhmen*, 36 (1912), No. 4, pp. 193-210, figs. 4; *abs. in Bot. Centbl.*, 119 (1912), No. 21, p. 541).—Determinations on a large number of sugar beets are said to have shown that the weight of these roots is more readily modified than is the sugar content. The experiments did not tend to support the statement that the greater the weight the less the sugar content, except in extreme and hence rare cases.

**The variability and relationship of weight and sugar content of sugar beets,** K. ANDRLÍK, V. BARTOŠ, and J. URBAN (*Ztschr. Zuckerindus. Böhmen*, 36 (1912), No. 4, pp. 193-210, figs. 4).—Tables and charts present data obtained in statistical studies of the weight and sugar contents of various strains of sugar beets.

From data presented, the authors conclude that the weight of the beet root shows fluctuating variability in accordance with the Quetelet-Galton law. Each strain shows its own correlation between root weight and sugar percentage. In only a few unusual cases does it occur that low sugar content accompanies a very unusual root weight, and these cases probably result from abnormalities in the use of plant food.

**Contribution on the relation between the sugar content and weight of sugar beets,** K. NOVOTNÝ (*Ztschr. Zuckerindus. Böhmen*, 36 (1912), No. 5, pp. 269-272).—This article presents the results of a further investigation and verifies the conclusions of the paper noted above.

**Recent chemical and physiological investigations on the sugar beet** (*Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases*, 3 (1912), No. 4, pp. 907-911).—The results of a number of recent investigations are given tending to the following general conclusions:

"It may be considered as settled that a want of light is injurious to the beet crop, giving . . . a product of low industrial value. While it can not be denied that sugar, as saccharose, is formed in the organs of assimilation of the beet, it is not equally certain that it circulates as such in its passage to the organs of reserve. There is no doubt that beets in the second year of growth can produce and store sugar. In general, the correlation between the decrease in sugar content and the increase of weight of root does not hold good. With a perfect selection (élites) the injurious influence of root weight on sugar content can be eliminated."

A bibliography is appended.

**Influence of light on the development of the sugar beet,** A. STIFT (*Osterr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 49 (1911), No. 6, pp. 849-856).—The

author summarizes some work of others upon this subject. In his own experiments he found that the weight per plant of the leaves of the shaded samples selected ranged from 188 to 198 gm., as compared with from 221 to 504 gm. in case of the unshaded samples. The weights per root ranged from 51.6 to 81.6 gm. and from 202.3 to 743 gm. in case of the shaded and unshaded beets, respectively. The leaf weight was from almost  $2\frac{1}{2}$  to about  $3\frac{3}{8}$  times as great as the root weight of the shaded samples and from about  $\frac{1}{2}$  to  $1\frac{1}{2}$  times as great as the root weight in case of the unshaded samples. The sugar content of the shade-grown roots averaged 13.9 per cent, while that of the unshaded roots ranged from 10.8 to 12.9 per cent. The sugar production per shade-grown root averaged 9.2 gm. but ranged from 25.5 to 85.4 gm. in case of the unshaded roots.

The author presents computations from the work of Briem which indicate that the shade-grown roots had a greater average leaf weight and a much smaller average root weight than did the unshaded beets. The work of Strohmmer verified this result, and indicated a somewhat lower average sugar content in case of the shade-grown beets and a much lower sugar production per beet.

Other work on this subject has already been noted (E. S. R., 25, p. 236).

[Manganese as a sugar beet fertilizer], E. ZACHAREWICZ (*Rev. Vit.*, 37 (1912), No. 955, pp. 471-473).—Three sugar beet varieties gave higher yields on plots that had received manganese at the rate of 150 kg. per hectare (133.5 lbs. per acre) than they did on the check plots. Two other varieties gave higher yields on the check plots. Analyses showed similarly variable results as to density, purity quotient, and the sugar and dry matter percentages.

Report on sugar experiments, 1910-11 (*Bul. Dept. Agr. Jamaica, n. ser.*, 2 (1912), No. 5, pp. 1-27).—This is a report of variety and fertilizer tests with sugar cane conducted on a number of estates in Jamaica. Tables state the results of mechanical and chemical analyses of soils of different estates and the cane yields obtained after various fertilizer applications.

Timothy production on irrigated land in the Northwestern States, M. W. EVANS (*U. S. Dept. Agr., Farmers' Bul.* 562, pp. 32).—This publication discusses the growing of timothy in mixture with alfalfa in place of clover, a practice at present used in only a few of the more important timothy-producing centers, though well adapted to conditions on most of the irrigated land where timothy is produced, and describes the methods of seeding, irrigating, cultivating, fertilizing, harvesting, and marketing the crop, together with the treatment and management of established timothy meadows and the crop rotations followed in the region.

[Canada weeds and weed seed] (*Canada Dept. Agr., Seed Branch. Bul.* 8-6, 1911, pp. 70, figs. 177).—The author divides this bulletin into 3 parts: (1) The Seed Control Act, 1911, and Regulations Made by the Governor in Council (pp. 3-10); (2) Seed Samples for Purity and Germination Tests (pp. 11-21); and (3) Weeds and Weed Seeds (pp. 22-67). The third part gives descriptions and illustrations of numerous weeds and weed seeds and brief notes on them.

The eradication of wild onion, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 404-409).—Land on which wild onions had grown did not produce a single onion strong enough to set seed during 2 years after it had been treated to a mixture of 14 lbs. orchard grass, 7 lbs. tall fescue, 7 lbs. tall oat grass, 1 lb. rough-stalked meadow grass, 3 lbs. chicory, 8 lbs. burnet, 1 lb. yarrow, 3 lbs. kidney vetch, 1 lb. alsike clover, 2 lbs. late-flowering red clover, and 2 lbs. of white clover, or 49 lbs per acre in all.

Among other methods of eradication tested in pot and plat experiments were applications of lime, gas lime, carbolic acid, sulphocyanid of ammonium, sulphuric acid, arsenic, sulphate of copper, common salt, sulphate of magnesia,

chlorid of magnesium, carbolized lime, and various other materials. Cutting off the flowering heads, pulling up the plants by hand, deep plowing, and burning the soil were also tried without success.

The only field methods which seemed to promise any real success consisted in "lightening the soil by road drift" and "raising the top 8 in. of soil and putting 3 in. depth of ashes below it." "While the use of road drift certainly did good, it was not nearly as good as the employment of ashes." The author regards these results as indicating that the solution of the problem must lie "in the direction of finding some means by which the soil could be rendered lighter and less retentive of water."

## HORTICULTURE.

**Library of agriculture.**—**Horticulture and truck farming**, H. M. SKINNER and A. L. MCCREDIE (*Chicago, 1912, vol. 4, pp. 539, pls. 17, figs. 145*).—This, the fourth of a series of volumes dealing with agricultural subjects, consists largely of papers which have previously appeared as bulletins of the U. S. Department of Agriculture and of some of the State stations.

**Plant protection calendar for field, vineyard, orchard, and garden** (*Pflanzenschutzkalender für Feld-, Wein-, Obst- und Gartenbau. Vienna: K. K. Landw. Bakt. u. Pflanzenschutzstat., 1911, pp. 11*).—This calendar outlines the necessary operations throughout the year for combating insect pests, fungus diseases, and other enemies for greenhouse, garden, and field crops.

**Influence of fertilizers on the conservation of fruits**, N. ESPAULLARD (*Jour. Soc. Nat. Hort. France, 4. ser., 13 (1912), July, pp. 470, 471*).—The author here summarizes the results secured in a 3-year study of the effect of various fertilizer elements on the keeping quality of pears.

The phosphatic and potassic fertilizers were found to produce large handsome fruits without impairing their keeping quality. The use of nitrate of soda alone, however, resulted in shriveled fruit of poor keeping quality. Nitrate of soda appears to stimulate vegetative growth and to hasten maturity at the expense of quality of the fruit.

**Profitable fruit storage cellar**, W. J. LEWIS (*New England Homestead, 65 (1912), No. 8, pp. 140, 142, fig. 1*).—A fruit storage cellar capable of holding about 6,000 bu. of apples is here described and illustrated.

**Orcharding in Maine**, A. K. GARDNER and H. P. SWEETSER (*Bul. [Maine] Dept. Agr., 11 (1912), No. 3, pp. 52, figs. 11*).—A popular treatise on apple orcharding.

**How to make an orchard in British Columbia**, J. T. BEALBY (*London, 1912, pp. 86*).—A popular handbook dealing especially with orchard practices in British Columbia.

**The Georgia apple**, E. M. HAFFER (*Proc. Ga. State Hort. Soc., 36 (1912), pp. 46-52*).—A general discussion of apple culture in the Georgia mountains, including a descriptive list of native Georgia apples.

**Pruning olives in Italy**, N. PINTO (*Bol. Arbor. Ital., 7 (1911), Nos. 2, pp. 55-65; 3-4, pp. 149-178, figs. 2*).—A descriptive account of the methods employed in pruning olives in the Province of Bari, Italy.

**Contribution to the study of the reconstitution of vineyards.**—**I. The grape scions, or a sketch of the ampelography of Vaud**, J. BURNAT and I. ANKEN (*Contribution à l'Étude de la Reconstitution des Vignobles. I. Les Cépages-Greffons ou Essai d'Ampélographie Vaudoise. Geneva and Paris, 1910, pp. XVII+126, pls. 16*).—This is the first of a series of 3 volumes to deal with the reconstitution of vineyards in the Vaud region. The present volume contains a study of the varieties of grapes grown in this region that have furnished the

scions in the reconstitution of vineyards with American stocks. The succeeding volumes will deal with the results secured with various stocks, scions, and direct bearers.

**American stocks for Cape vineyards,** A. J. PEROLD and I. TRIBOLET (*Agr. Jour. Union So. Africa*, 4 (1912), Nos. 1, pp. 99-109; 2, pp. 222-257).—This comprises a report of an inquiry into the suitability of the American stocks on which the vineyards in the Cape Province have thus far been reconstructed.

**Fruits of warm countries.—I, A general study of the fruits,** P. HUBERT (*Fruits des Pays Chauds. I, Étude Générale des Fruits. Paris, 1912, pp. X+728, figs. 227*).—This is the first volume of a 2-volume work dealing with the principal fruits of tropical and subtropical regions. Especial attention is given to the more widely distributed table fruits, including those susceptible to large local consumption and those suitable for developing an export trade. A discussion under each kind of fruit deals more or less in detail with its history, distribution, synonymy, botany, varieties, culture, enemies, uses, and commerce.

A succeeding volume is to treat in detail of the fruit industries in warm climates.

**Manurial experiments on cacao in Trinidad,** J. DE VERTEUIL (*West Indian Bul.*, 12 (1912), No. 3, pp. 320-344).—A description, including the results to date, is given of manurial experiments on cacao and Castilla rubber being conducted on various estates in Trinidad, both by the Trinidad Department of Agriculture and the Trinidad Board of Agriculture. No conclusions are drawn.

**The date palm (*Phoenix dactylifera*) in Egypt,** A. PAOLETTI (*Agr. Colon. [Italy]*, 6 (1912), No. 6, pp. 248-258).—An account of date culture in Egypt, including also brief notes on the varieties grown.

**The planting and care of shade trees (Trenton, N. J.: Forest Park Reserv. Comm., 1912, pp. 128, pls. 5, figs. 43).**—This comprises the 3 following papers, the first two of which were originally published in the report of the Forest Park Reservation Commission of New Jersey for 1908 and are here thoroughly revised: The Planting and Care of Shade Trees, by A. Gaskill and J. O. Hazard (pp. 7-65); Insects Injurious to Shade Trees, by J. B. Smith (pp. 67-91), previously noted (E. S. R., 25, p. 254); and Diseases of Shade and Forest Trees, by M. T. Cook (pp. 93-124).

**The pecan,** C. A. REED (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 251, pp. 58, figs. 25*).—A practical treatise on the pecan and its culture, discussed under the following general headings: Botanical classification of the pecan, natural distribution, habit of growth, flowering habit, decrease in number of native trees, cultural distribution, extent of planting, economic importance, culture, propagation, stocks for grafting and budding, planting, nut handling, and varieties.

**Making a garden of perennials,** W. C. EGAN (*New York, 1912, pp. 52, pls. 8*).—A short cultural treatise including lists of dependable perennials for different soils and situations.

**Molding concrete flower pots, boxes, jardinières, etc.,** A. A. HOUGHTON (*New York, 1912, pp. 52, figs. 8*).—A practical treatise explanatory of the construction of the molds for and the construction of various designs of concrete flower pots, jardinières, and window boxes of concrete, together with the reinforcement and surface treatment of the casts after molding.

**Molding concrete fountains and lawn ornaments,** A. A. HOUGHTON (*New York, 1912, pp. 56, figs. 14*).—A practical treatise illustrating and explaining in detail the molds for and the methods of molding various styles of concrete fountains, lawn seats, curbing, hitching posts, pergolas, sundials, lawn vases, and other ornamental garden furniture of concrete.

## FORESTRY.

**Forestry in New England**, R. C. HAWLEY and A. F. HAWES (*New York and London, 1912, pp. XV+479, pls. 2, figs. 140*).—Part 1 of this work furnishes the woodland owner a brief survey of the whole field of industry and provides him with a working knowledge of forestry. The successive chapters discuss silvics, silvicultural systems, silvicultural characteristics of the important New England trees, forest planting and seeding, improvement cuttings, injuries from animals, forest insects and fungi, forest fires, timber estimating and valuation, and growth of trees and forests.

Part 2 deals with New England forests and their management, the subject matter being discussed under the following chapter headings: The original forests and their early development, present forest conditions, the spruce region, the northern hardwoods region, the white-pine region, the sprout hardwoods region, the progress of forestry in New England, and the yield to be expected from New England forests under proper management.

**Report on timber conditions around Lesser Slave Lake**, D. R. CAMERON (*Dept. Int. Canada, Forestry Branch Bul. 29, 1912, pp. 54, pl. 1, figs. 17*).—This comprises a detailed report of a reconnaissance survey made during the summer of 1911. The general conditions of the region are described and the country examined is discussed by districts. Proposed forest reserves are suggested and a scheme of fire protection, illustrated by a map, is also submitted. A number of tables summarizing the important information about the country are appended.

**The forest trees of Britain**, C. A. JOHNS, revised by G. S. BOULGER (*London and Brighton, England, 1912, 10. ed., pp. XIV+431, pls. 32, figs. 152*).—A revised edition of the late author's work, which is essentially a handbook of popular information relative to the lore, distinguishing characteristics, adaptation, and planting value of the principal trees and shrubs grown in England. See also a previous note (E. S. R., 26, p. 642).

**Notes on Kerry woods, illustrating methods of collecting and utilizing information for a forest survey**, R. L. ROBINSON (*Jour. Bd. Agr. [London], 1912, Sup. 9, pp. 64, pls. 7, figs. 4*).—The investigations described were primarily undertaken with the object of obtaining some accurate figures relating to the growth of timber in one of the more hilly districts of Wales. The scope of the work was broadened in order to settle the lines on which a forest survey on a large scale should proceed.

The introductory chapter deals with the topography, climate, geology, and soil of the Kerry woods. The succeeding chapters discuss the methods of measurement and details of growth of different species, together with the utilization of the data for the survey.

**Complete yield tables for British woodlands and the finance of British forestry**, P. T. MAW (*London, 1912, pp. XII+108, figs. 36*).—This comprises the results of the author's investigations concerning the growth of timber in Great Britain and the financial returns to be obtained therefrom. The tables as given for both deciduous and coniferous trees on different qualities of soil show for various aged stands the amount and value of thinnings removed, crop left after thinning, increment, land rentals per annum from date of planting, and the annual income from a normally stocked forest.

**Taxation investigations.**—III, **Determination of the form of standing trees**, T. JONSON (*Skogsvårdsför. Tidskr., 1912, Fackafd., No. 4, pp. 235-275, figs. 11*).—The author's method of determining the total cubical content of standing trees, yield, and increment for the purpose of taxation is described.

**A method of investigating yields per acre in many aged stands**, H. H. CHAPMAN (*Forestry Quart.*, 10 (1912), No. 3, pp. 458-469, figs. 3).—The author discusses the principles involved in determining the area occupied by each age class in a managed forest and gives the details of a plan applied to uneven aged stands of shortleaf pine in Arkansas.

**On the arrangement of silvicultural experiments and the classes of forest yield tables**, VATER (*Tharand. Forstl. Jahrb.*, 63 (1912), No. 3, pp. 252-264).—A discussion of methods of conducting silvicultural experiments.

**Seventh annual report of the Forest Park Reservation Commission of New Jersey for the year ending October 31, 1911** (*Ann. Rpt. Forest Park Reserv. Com. N. J.*, 7 (1911), pp. 92, pls. 14).—This contains a summarized report of the work of the Forest Commission (pp. 9-18), together with the following detailed reports: The Forest Fire Service, by C. P. Wilber (pp. 19-67), and Report of the State Forester, by A. Gaskill (pp. 68-90).

**Progress report of forest administration in the Province of Eastern Bengal and Assam for the year 1910-11**, A. V. MONRO and H. CARTER (*Rpt. Forest Admin. East. Bengal and Assam, 1910-11*, pp. 92, pl. 1).—This is the customary report relative to the constitution, management, and administration of the state forests of Eastern Bengal and Assam, including the financial results for the year. All of the important data are appended in tabular form.

**Report on state nurseries and plantations for the year 1909-10**, W. C. KENSINGTON (*New Zeal. Dept. Lands, Rpt. State Nurseries and Plantations, 1909-10*, pp. 38, pls. 6).—This comprises the combined reports of the superintending nurserymen of the New Zealand forest nurseries and plantations under their supervision for the financial year ended March 31, 1910.

**Emory oak in southern Arizona**, F. J. PHILLIPS (*U. S. Dept. Agr., Forest Serv. Circ. 201*, pp. 15, pls. 5).—An account is given of the Emory oak (*Quercus emoryi*) relative to its range and occurrence, climate, soil and moisture requirements, associated species, characteristics of the tree, causes of injury, utilization, and management.

**Report on the investigation of bamboo as material for production of paper pulp**, W. RAITT (*Indian Forest Rec.*, 3 (1912), No. 3, pp. 37, pls. 2).—This comprises a report of investigations conducted under the direction of the Forest Research Institute to determine the suitability of 5 different species of bamboo for the manufacture of cellulose at a marketable cost.

The author found that where the cost of delivery to mill sites is not excessive, all 5 species are suitable for the manufacture of cellulose, and that all the species, except one, may be mixed in treatment. The culms of all ages may be mixed indiscriminately in treatment, and nodes need not be rejected, providing the following treatment is adopted: Culms not to be cut until the shoots of the year are full-grown; a period of seasoning of not less than 3 months to elapse before they are used; crushing; extraction of starchy matter; and digestion with sulphate liquor. Neither the sulphite nor the soda process was found to be economical in the production of cellulose from bamboo.

**Rubber: Its culture and preparation**, K. W. WOLF-CZAPEK (*Der Kautschuk: Seine Gewinnung und Verarbeitung. Berlin, 1912*, pp. 132, figs. 51).—This comprises a concise handbook of information relative to the collection, preparation, commerce, and chemistry of rubber, as well as the vulcanization and manufacture of soft and hard rubber articles.

A short bibliography is appended.

**[Rubber in the Federated Malay States]**, L. LEWTON-BRAIN (*Fed. Malay States, Rpt. Dir. Agr., 1911*, pp. 1-10).—A report on rubber culture in the Federated Malay States for the year 1911, which discusses acreages, cultiva-

tion, manufacture, insect pests, and diseases. The total acreage planted with rubber at the end of 1911 was 352,974 as compared with 245,774 acres in 1910.

The excretion of serum from moist rubber after pressing, A. ZIMMERMANN (*Pflanze*, 8 (1912), No. 7, pp. 389-398).—In experiments conducted to determine a method of preventing further excretion of moisture from rubber after being pressed, a method devised by D. Sandmann, which consists in immersing the pressed rubber in boiling water for a short time, was found to reduce materially the subsequent excretion of serum. The author suggests the need of further experiments to determine the effect of the boiling water on the physical properties of rubber.

Commercial creosotes with special reference to protection of wood from decay, C. P. WINSLOW (*U. S. Dept. Agr., Forest Serv. Circ. 206, pp. 38, figs. 17*).—In continuation of previous investigations relative to the properties, methods of analysis, etc., of various creosotes (E. S. R., 19, p. 812), the results to date are here presented of an investigation of the quality and prices of commercial creosotes.

An account is given of the more important sources of wood-preserving creosotes, methods used in their production, their general properties and the quality, price, and quantity of the creosotes annually consumed in this country. A series of fractional distillation and index of refraction curves are given for samples classed as coal-tar creosotes and mixed coal-tar creosotes. Samples of a large number of authentic coal tars, oil tars, and wood tars have been collected from which creosotes are being distilled and critically analyzed and examined. A number of these samples are here classified and described in tabular form, the data given showing the character of the oil, the fractions, and the residue, together with the sulphonation residues of fractions.

The method used in analyzing the creosotes discussed is appended.

Bibliography on forestry published during 1911 (*Skogsvårdsför. Tidskr., 1912, Fackafk., No. 3, pp. 217-232*).—The bibliography includes literature on forestry topics published in the German, French, English, and Scandinavian languages.

## DISEASES OF PLANTS.

The relation of certain parasitic fungi to the age and development of the host plant, M. T. COOK and J. J. TAUBENHAUS (*Abstr. in Phytopathology, 2 (1912), No. 2, p. 98*).—According to the authors, experiments have proved that laboratory inoculations made on picked fruits or detached portions of plants are not sufficiently reliable for definite conclusions. It has been found that there is a difference in resistance between picked fruits kept in the laboratory and unpicked ones, and between young and older fruits of the same tree, as well as between fruits of different varieties. This resistance is held to be intimately associated with the cell contents of the host. It is believed that *Glomerella rafomaculans* of the apple is able to attack many different hosts and that this explains the presence of so many so-called new species.

Studies on the biology and morphology of *Kuehneola albida* and *Uredo mülleri*, S. STRELIN (*Mycol. Centbl., 1 (1912), No. 5, pp. 131-137*).—From his investigations the author concludes that these are two developmental forms of one and the same fungus.

Notes on some heteroecious rusts of Connecticut, G. P. CLINTON (*Abstr. in Phytopathology, 2 (1912), No. 2, p. 94*).—The author reports the teleutospore stage of *Gymnosporangium japonicum* for the first time in America, it having been collected on two different importations of *Juniperus chinensis* from Japan. *Peridermium peckii* is shown by artificial inoculations to be the aecial stage of *Pucciniastrum myrtilli*. *Pinus austriaca*, *P. maritima*, and *P. ponderosa* are

reported as new American hosts for *Peridermium pyriforme*. Notes are also given on species or stages of fungi not previously reported from Connecticut.

**The development of *Glæosporium malicorticis*.** H. S. JACKSON (*Abt. in Phytopathology*, 2 (1912), No. 2, p. 95).—A description is given of the perfect or ascospore stage of *G. malicorticis*, which the author has been having under observation for a number of years.

Pure cultures of the ascospores were made, and inoculation experiments showed that it takes one year for the cankers to mature. All inoculations produced typical cankers, which bore conidia typical of *G. malicorticis*.

Attention is called to the resemblance both in conidial and ascospore stages to the fungus *Pseudopeziza ribis*. The exact generic position of the fungus is somewhat doubtful, but it is described as *Neofabrea malicorticis*, a new combination.

**The structure and development of crown gall: A plant cancer.** E. F. SMITH, NELLIE A. BROWN, and LUCIA McCILLOCH (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 255, pp. 60, pls. 109, figs. 2*).—This bulletin is in continuation of one previously issued (*E. S. R.*, 25, p. 243), and gives detailed descriptions of a large number of plates made in studying this disease, the histological evidence being based upon them.

[**Crown gall on mangolds in England**], R. H. BIFFEN (*Jour. Roy. Agr. Soc. England*, 72 (1911), p. 378, fig. 1).—A tumor-like outgrowth on the roots of mangolds observed in 1910, and more closely studied in 1911, is found to be a case of crown gall ascribed to *Bacterium tumefaciens*. This disease has been certainly identified only in Norfolk and Shropshire, but is suspected to exist on raspberry roots in Cambridgeshire. Further investigations are contemplated.

**On two injurious fungi of garden plants,** G. KÖCK (*Separate from Bl. Obst. Wein, Gartenbau u. Kleintierzucht*, 1911, No. 11, pp. 3).—The author discusses briefly a fungus sent him for examination from Silesia on a species of *Erica*, supposed by him to be *Oidium ericinum*, also a myxomycete, said to be *Spumaria alba*, found on young asters and spreading in manure beds. The results of his measurements and observations are also given.

**Treatment of seed wheat for smut** (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 5, p. 396).—Trials were made with 0.5 per cent, 1 per cent, 1.5 per cent, and 2 per cent solutions of bluestone, and also of the effect of dipping the wheat in limewater afterwards.

These tests showed that any solution of bluestone stronger than 1.5 per cent is likely to affect seriously the germination of the grain, and even at this strength it is advisable to dip the wheat in a mixture of 1 lb. lime to 20 gal. of water.

**Trials of alleged preventives for smut in wheat** (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 5, p. 394).—This is a summary of reports from experiments at the Cowra, Wagga, and Bathurst experiment farms with two commercial preparations, claimed to prevent smut in wheat, as compared with bluestone (2 per cent) and limewater.

One of these was found to be equal to bluestone as a protective, but both affected the germinating power to a greater extent, so that neither is recommended as a substitute for bluestone.

**The diseases of ginseng and their control,** H. H. WHETZEL and J. ROSENBAUM (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 250, pp. 44, pls. 12, figs. 5*).—This is a second attempt to bring together the information relating to the diseases of the drug plant known as ginseng, the first publication having been previously noted (*E. S. R.*, 16, p. 271). The data presented on each disease are arranged under the heads of history, symptoms, cause, and control. Among the

diseases described are *Alternaria* blight, *Phytophthora* mildew, *Vermicularia* stem anthracnose, *Pestalozzia* leaf anthracnose, papery leaf spot, injury caused by cold following the use of Bordeaux mixture, the damping off of seedlings due to *Rhizoctonia*, *Pythium*, etc., wilts due to *Acrostalagmus* and *Fusarium*, nematode root galls, and root rots due to a number of causes. The spraying of ginseng, soil sterilization, relation of fertilizers to diseases, and the drainage of ginseng beds are also discussed.

**An external dry rot of potato tubers.** MISS C. O. JAMIESON and W. H. WOLLENWEBER (*Jour. Wash. Acad. Sci.*, 2 (1912), No. 6, pp. 146-152, fig. 1; *abs. in Mycol. Contribl.*, 1 (1912), No. 6, p. 180).—A *Fusarium* was found on potatoes affected with dry rot which was proved by inoculation experiments to be a wound parasite capable of causing this disease. The fungus is claimed to be a new species, distinguished by its two forms of conidia, and is described by the authors under the name *F. trichothecioides* n. sp. It is claimed that the disease is clearly differentiated from the wilt and dry rot ascribed to *F. oxysporum*.

**The relationship of *Oospora scabies* to the higher bacteria.** G. C. CUNNINGHAM (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 97).—A study of cultures of the organism causing the potato scab has led to the conclusion that the organism should be placed in the genus *Streptothrix*, one of the higher bacteria.

**Biochemical research on leaf-roll of potato.—III. Chemical characters.** G. DOBY (*Kisérlet. Közlem.*, 15 (1912), No. 2, pp. 210-222; *Ztschr. Pflanzenkrankh.*, 22 (1912), No. 4, pp. 204-211).—Further analyses (E. S. R., 26, p. 547) lead the author to conclude (1) that the chemical composition of tubers affected with this disease shows different variations from those observed in the case of sound ones, but that the limits of such variations are as yet difficult to determine on account of complications arising from such influences as soil, weather, variety of potatoes, etc.; (2) that the diseased tubers show a lower average in dry substance, ash, protein, and carbohydrates as a whole; (3) that the sound and diseased tubers differ most in the total and the composition of their dry substance and in starch; and (4) that the biochemical processes are more retarded in diseased than in sound plants, but that it is probably not yet practicable to distinguish diseased potatoes on the basis of chemical analyses alone. The results are given in tabulated form.

**Treatment of seed potatoes with formalin** (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 5, p. 408).—In an experiment at the Bathurst Experiment Farm, seed potatoes treated with formalin to prevent the development of scab and other diseases were practically a failure, while plots of untreated seed germinated well.

**Gummosis.** L. P. DE BUSSY (*Meded. Deli-Proefstat. Medan*, 6 (1911), No. 2, pp. 77-89).—An account of studies carried on during 1910-11 on gummosis of tobacco.

This disease is claimed to be caused in case of the plants studied by *Bacillus solanacearum*, which is alleged to attack also other plants. Artificial inoculations, it is stated, developed infection in case of potato, indigo, sesame, tomato, and other economic plants. The details are given of investigations carried out on the influence of cultivation and manuring on the progress of the disease.

**The Deli form of *Bacillus solanacearum*.** J. A. HONING (*Meded. Deli-Proefstat. Medan*, 6 (1912), No. 7, pp. 219-250).—This is a detailed account of the author's studies on the morphological and physiological characters of *B. solanacearum*, claimed to cause gummosis of tobacco and other plants at Medan, and a detailed comparison of these characters with those of *B. nicotianæ*, said to cause a like disease of tobacco in Japan. The conclusion is reached that the two properly belong to the same species, the former being probably a somewhat weakened form of the species.

**A serious root disease of radish**, J. T. BARRETT (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 96).—A disease of radishes, characterized by a peculiar browning or blackening of a portion or all of the root, is described. The infected tissue in the early stages of the disease remains sound and brittle, but as the disease progresses the cells are broken down and rots due to saprophytic forms frequently set in. The organism which causes the disease is said to be *Aphanomyces levis*, long known as a saprophyte inhabiting the soil and water. No successful means of control have yet been determined.

**Tomato leaf rust** (*Jour. Bd. Agr. [London]*, 18 (1912), No. 11, pp. 920, 921, pl. 1; *abs. in Mycol. Centbl.*, 1 (1912), No. 6, p. 181).—Leaves, stems, and occasionally fruits are attacked by this disease, ascribed to *Cladosporium fulvum*. Fungicides avail only when applied to germinating spores. The entire surface of the tomato plant should, therefore, be covered frequently with half-strength Bordeaux mixture if the plants are young, but with potassium sulphid solution (1 oz. in 4 gal. of water) if flowers and young fruit are present.

**Treatment of chlorosis in fruit trees and vines**, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz*, n. ser., 10 (1912), No. 5, pp. 49-51).—In continuation of previous studies (*E. S. R.*, 25, p. 518), experiments were made in supplying iron and other salts to chlorotic trees and vines. The salts were made up into a mash or porridge with water and introduced into holes bored in the trunks, the holes being afterwards closed with corks and tree wax. With the exception of a few cases in which the holes are thought to have been in dead tissue, the experiments were considered successful, being followed by the restoration of the green color and by luxuriant growth.

**Oily or glassy fruits**, I. GROSS (*Prakt. Bl. Pflanzenbau u. Schutz*, n. ser., 10 (1912), No. 5, pp. 56, 57).—Attention is called to an oily or glassy appearance said to be confined almost exclusively to apples. This is noted in spots on the surface or beneath the skin, injuring the appearance and sometimes the flavor of the fruit. It is said that frequently as much as 5 per cent of the fruit is thus affected, and sometimes a much larger proportion, the trouble being especially noteworthy in 1911.

**Inoculation experiments with fungi associated with apple leaf spot and canker**, C. E. LEWIS (*Phytopathology*, 2 (1912), No. 2, pp. 49-62).—The author began in 1908 a study of the fungi associated with apple diseases in Maine orchards, and in the present paper the results of inoculations with fungi isolated from diseased branches and leaves are given.

A considerable portion of the leaf spot which occurs in Maine orchards is said to be due to the fungus *Sphaeropsis malorum*, although similar spotting has been observed in orchards which is attributed to injury due to spraying with Bordeaux mixture. Thus far, *Sphaeropsis* has been the only fungus isolated from apple leaves in the State which has caused spotting on the leaves when inoculations were made from pure cultures. *Phyllosticta limitata*, *Coniothyrium pirina*, and *Coryneum foliicolum* grew and fruited on dead spots when the spores were sprayed on the leaves, but no new spots were produced.

A number of fungi have been found to occur on branches and twigs of the apple. Of these *Sphaeropsis* does the greatest damage, but it has been proved by inoculation experiments that *Coryneum* and *Phoma* can cause considerable injury to the young trees and branches of orchard trees. *Myxosporium* and *Cytospora*, it is claimed, do not attack healthy branches, but may attack weakened ones.

**Some notes on *Sphaeropsis malorum***, C. BROOKS and MARGARET DEMERITT (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 94).—The authors report having isolated two forms of *Sphaeropsis* from decaying apples. One produces spores typical of *S. malorum*, while the other has spores that are longer and more

oblong in outline. The two forms retain their distinctive characteristics when grown on the same culture medium. Both have been obtained from the fruit. The pycnidia from cankers have nearly always contained the long spores. In inoculations on foliage, positive results have been obtained only with the long-spored form. The large number of leaf spots beneath cankers are believed to furnish evidence of the transfer of the fungus from the limb to the leaves.

**Apple fruit spot and quince blotch, C. BROOKS and CAROLINE A. BLACK** (*Phytopathology*, 2 (1912), No. 2, pp. 63-72, pls. 2).—This paper includes a second report on the fruit spot of apples (E. S. R., 20, p. 847) and a discussion of a similar disease of quinces.

A *Phoma* stage has been found for the fungus causing the fruit spot of apples, and as a consequence the name of the fungus has been changed from *Cylindrosporium pomi* to *Phoma pomi*. A spot similar to that on apples is reported on quinces, and cross inoculations have shown that it is due to the fungus mentioned above. This disease has been previously noted (E. S. R., 4, p. 656).

**Three destructive diseases of the peach, E. O. ESSIG** (*Mo. Bul. Com. Hort. Cal.*, 1 (1912), No. 8, pp. 337-359, figs. 4).—These diseases are peach yellows, peach rosette, and little peach. In case of each an account is given of the history of the disease, its destructiveness, distribution, the plants attacked, nature and symptoms of the disease, its modes of distribution, and recommendations looking to its control. To this is added the author's correspondence with various sources of information, also the California state quarantine law relating to peach yellows and rosette.

**The method of spreading of the olive knot disease, W. T. HORNE, W. B. PARKER, and L. L. DAINES** (*Abstr. in Phytopathology*, 2 (1912), No. 2, p. 96).—This is a progress report on studies carried out near Sacramento, Cal., to discover a method for controlling the olive knot disease due to *Bacterium savastanoi*.

No biting or piercing insect or other transporting agent was discovered, but it was found that vigorous knots exude bacterial slime when wet. It was demonstrated, both by platings from the slime and from direct inoculations, that this slime contains the organism in abundance, and its dissemination is accounted for by the spattering of rain, and the accidental transfer by birds, insects, or other agencies. Entrance into the living bark is believed usually to take place on healed wounds.

**Comparative experiments with certain sprays for controlling *Peronospora viticola* on the grape, A. BRETSCHNEIDER** (*Ztschr. Landw. Versuchsw. Österr.*, 15 (1912), No. 2, pp. 147-152).—This series of experiments repeats with certain extensions previous ones already noted elsewhere (E. S. R., 25, p. 751), results being given in detail with discussions of comparative cost in employment of the various preparations tested.

**The downy mildew fungi and their control, A. BRETSCHNEIDER** (*Monatsh. Landw.*, 5 (1912), No. 5, pp. 138-147, figs. 6).—Continuing the above the author gives a brief discussion of certain *Peronosporaceæ* as enemies of various fruits, trees, wild plants, etc., with recommendations as to preventive and remedial measures.

**A knot of citrus trees caused by *Sphæropsis tumefaciens*, FLORENCE HEDGES and L. S. TENNY** (*U. S. Dept. Agr., Bur. Plant Indus. Bul.* 247, pp. 74, pls. 10, figs. 8).—This bulletin gives an account of an infectious disease of citrus trees which has caused extensive losses in Jamaica. The same or a similar trouble has been recently discovered in the United States. The investigations reported have extended through a period of 6 years, during which time the

cause of the disease has been established by means of repeated inoculations, reisolations, and reinoculations.

The fungus causing the disease, *S. tumefaciens*, has been isolated from knots on lime and orange trees, and small knots have been also obtained from pomelo, lemon, tangerine, and *Citrus trifoliata*. The fungus penetrates the tissues far beyond the original point of infection, and a badly infected tree is a mass of tumors, sometimes not more than half an inch separating them. On the other hand, there may be considerable distance between two secondary tumors with no external evidence of the fungus, but microscopical examination reveals its presence in small quantities throughout the intervening portion of the stem. Occasionally an abnormal number of new shoots grow from the knots, forming witches' brooms, and this is said to be a characteristic of the disease under favorable conditions. Ultimately that portion of the branch above the knot dies.

Notes are given on the life history of the fungus, which was found to live for several years in the host.

It is suggested that affected limbs be removed, cutting them well below the lowest knots, and that badly diseased trees be uprooted and burned.

**Citrus scab.** H. S. FAWCETT (*Florida Sta. Bul.* 109, pp. 47-60, figs. 8).—A description is given of the citrus scab, due to *Cladosporium citri*. This fungus has been isolated from sour orange leaves and cultivated, and infection experiments have been made demonstrating that it is the cause of the trouble described.

The fungus seems particularly injurious to sour orange and lemon sprouts, and the author recommends the destruction of these, together with spraying with ammoniacal copper carbonate or Bordeaux mixture. The copper carbonate solution is preferred since it usually does not cause an increase of scale insects as sometimes follows the use of Bordeaux mixture. Where the disease is very prevalent the first spraying should be done soon after the petals fall, followed by a second in 2 weeks or a month, and a third at a similar interval if necessary. New growth which comes out at unseasonable times and late bloom, locally known as "June bloom," are said to be most subject to infection, and these should be cut out and destroyed.

A bibliography is appended.

**Notes on some diseases of trees in our national forests, II.** G. G. HEDGCOCK (*Phytopathology*, 2 (1912), No. 2, pp. 73-80).—In continuation of a previous account (E. S. R., 23, p. 456), the author describes some diseases of deciduous and coniferous trees. The principal fungi attacking deciduous trees enumerated are *Polyporus dryophilus*, *P. texanus*, *P. sulphureus*, *Fomes igniarius*, *F. everhartii*, *F. nigricans*, *F. applanatus*, *F. fasciatus*, *F. fraxinophilus*, and *F. robiniae*, while on coniferous trees he notes the occurrence of *Trametes pini*, *P. schurcivitzii*, *F. laticis*, *Echinodontium tinctorium*, *P. sulphureus*, *P. amarus*, *Lentinus lepidus*, and *Hydnum coralloides*.

**The chestnut bark fungus, Diaporthe parasitica.** C. L. SHEAR (*Phytopathology*, 2 (1912), No. 2, pp. 88, 89).—A brief discussion is given of the generic and specific identification of this organism and its relation to some other fungi.

**Some observations on experiments with the chestnut bark disease.** J. F. COLLINS (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 97).—The author points out that the mycelium of this fungus, contrary to common belief, can penetrate and continue to grow in the wood under an old diseased spot after the infected bark has been removed and the surface of the wood treated with tar, paint, etc., and that fruiting pustules may at times be produced in abundance on bare wood; that summer spores are not as liable to be blown about by the wind as has been

previously considered; and that threads of summer spores are dependent mainly, if not wholly, upon moisture conditions for their development.

The chestnut bark disease in Massachusetts, A. H. GRAVES (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 99).—The distribution of this disease in Massachusetts is traced, and the author states that it would probably be practicable for the State to adopt control measures in the northern and eastern parts. Coppice was found to be no more susceptible than seedlings, but burned areas are more apt to be infected than those untouched by fire. The best time for locating the chestnut bark disease is said to be during the month of August.

Summer and fall observations on the growth of the chestnut bark disease in Pennsylvania, CAROLINE RUMBOLD (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 100).—The results of observations on the fungus extending from July to winter are given.

During the summer period the rate of growth of mycelium and production of spores is said to be affected principally by moisture, and this period lasts until the latter part of December. During the transition period the pustules darken in color, often fall off, the mycelium disappears, and the pycnidia become sterile. Specimens collected on the first of December in different parts of the State showed perithecia with ascospores.

Preliminary notes on a twig blight of *Quercus prinus*, DELLA INGRAM (*Abs. in Phytopathology*, 2 (1912), No. 2, pp. 96, 97).—A disease of the chestnut oak which was noted in the spring and summer of 1911 is described. The range of the disease has not been definitely determined, but it has been reported from Connecticut and from various points in Virginia, Maryland, and Pennsylvania.

When viewed at a distance the diseased trees have the appearance of having been attacked by fire blight, the branches and leaves having the brown, blighted appearance characteristic of that disease. The fungus *Dothiorella quercina* has been found associated with the disease and is believed to be the cause of the trouble.

Tannic acid as protection for oak wood against dry rot, C. WEHMER (*Mycol. Centbl.*, 1 (1912), Nos. 5, pp. 138-148, figs. 6; 6, pp. 166-174).—Pursuant to previous studies (E. S. R., 26, pp. 551, 752; 27, p. 355), the author experimented on the growth of *Merulius lacrymans* as affected by tannic and gallic acids in various cultures. Solutions of from 0.5 to 5 per cent strength were found to hinder or stop growth in nearly all solutions. Pine wood, ordinarily attacked and destroyed by this fungus, was protected by a 1 to 2 per cent solution. Practical applications are suggested.

Bacterial black spot of walnut, L. RÖDWAY (*Agr. Gaz. Tasmania*, 20 (1912), No. 3, pp. 85, 86, fig. 1; *abs. in Jour. Dept. Agr. So. Aust.*, 15 (1912), No. 10, p. 991).—The author notes the appearance of this disease in many of the walnut trees about Hobart. It appears first as small black spots on the surface of both nut and leaf. The disease spreads rapidly, involving finally all parts of both nut and leaf, weakening the tree so that death results in a few years. It appears to start on the surface from new infection each year, the parasitical bacteria gradually penetrating deeper layers of cells as the vitality of the tree becomes reduced by the disease. The trunk, however, does not seem to be attacked directly. It is thought that consistent spraying with Bordeaux mixture will greatly reduce the attack. Removal of infected parts in early stages of the disease is also recommended.

Peridermium cedri as a destructive fungus, R. S. TROUP (*Indian Forester*, 38 (1912), No. 5, pp. 222, 223, pl. 1).—This fungus, which produces the characteristic witches' brooms on Deodar trees in certain parts of the Himalayas

but which has hitherto been considered as practically harmless, is here stated to have been found by the author to cause needle-cast, resulting death of branchlets, cessation of growth in height, forking, and consequent worthlessness of the poles attacked. Removal of all infected parts and trees is suggested as a possible check to the disease.

**Parasitism of *Phoradendron juniperinum libocedri*, E. P. MEINECKE** (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 92).—The author briefly describes the occurrence of this parasite on *Libocedrus decurrens*. He concludes that as it is capable of living for a great number of years without developing any green exterior parts, the plant has become a true parasite.

**The use of fungicides to prevent damping off, C. HARTLEY** (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 99).—The author reports the serious damping off of pine seedlings in a nursery in western Nebraska, most of the disease being caused by *Pythium debaryanum*, although *Fusarium* and *Rhizoctonia* caused some damage.

Different methods of soil treatment were tested, and it was found that sulphuric acid gave the best results. This was applied in an aqueous solution at the time of seed sowing, about 0.2 fluid ounce being used per square foot of seed bed. Injury to seedlings is prevented by light watering twice daily until germination is complete.

**The detection of inert ingredients of fungicides, E. WALLACE and L. H. EVANS** (*Abs. in Phytopathology*, 2 (1912), No. 2, p. 95).—A brief account is given of work carried out for the Insecticide and Fungicide Board of this Department to test various substances in relation to their action on conidia of *Glomerella rufomaculans* and *Sclerotinia fructigena*.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

**Proceedings of the Seventh International Zoological Congress** (*Proc. 7. Internat. Zool. Cong., 1907* [pub. 1912], pp. 972, figs. 102).—Among the papers of interest to the economic zoologist and entomologist are the following: The Reactions of Sarcophagid Fly Larvæ to Light, by W. B. Herms (pp. 152, 153); The Immunity of Caterpillars of *Galleria mellonella* against Tubercle Bacilli and Some Other Microbes, by S. Metalnikoff (p. 282); The Immunity of Caterpillars of *G. mellonella* to Microbes and Their Diseases, by V. Nedrigailoff (p. 283); The Relations Between the Hemipterological Faunas of Europe and North America, by G. Horváth (pp. 560–571); The Recent Progress and Present Condition of Economic Entomology, by L. O. Howard (pp. 572–600); Polymorphism in Hemiptera and Some of Its Significances, by H. Osborn (pp. 601–603); The Influence of Minimum Temperatures in Limiting the Northern Distribution of Insects, E. D. Sanderson (pp. 604, 605), previously noted (E. S. R., 20, p. 851); A Contribution to Our Knowledge of Insecticides, by C. T. McClintock, E. M. Houghton, and H. C. Hamilton (pp. 613–628), previously noted (E. S. R., 25, p. 362); Eradication of The Southern Cattle Tick, by B. H. Ransom (pp. 648–655), previously noted (E. S. R., 24, p. 260); Notes on *Scutigercella immaculata*, its Eggs and Larvæ, by S. R. Williams (pp. 656–659); Ridding a State of Mosquitoes, by J. B. Smith (pp. 662, 663); A Problem in Antigeny, by C. H. Fernald (pp. 664–667); The Influence of Hibernation and Migration on Animal Parasites, by H. B. Ward (pp. 673–684); Geographical Variation in Birds with Special Reference to Humidity, by C. W. Beebe (699–701); and Distribution of Mosquitoes in North America, by H. G. Dyar (pp. 956, 957).

Proceedings of the First International Entomological Congress (1. Cong. Internat. Ent. Brussels, 1 (1910), pp. 277, pls. 5; 2 (1910), pp. 520, pls. 27).—Among the papers of interest to the economic entomologist, all of which are in the second volume, are the following: "Springtails" (Collembola): Their Economic Importance, with Notes on Some Unrecorded Instances of Damage, by F. V. Theobald (pp. 1-18); The Calliphorine Cutaneous Parasites of Domestic Animals, by L. Gedoelst (pp. 19-28); The Control and Disinfection of Imported Seeds and Plants, by D. Morris (pp. 33-40); The Distribution of the Yellow Fever Mosquito (*Stegomyia fasciata*) and General Notes on Its Bionomics, by F. V. Insects injurious to corn, D. T. FULLAWAY (*Hawaii Sta. Bul.* 27, p. 20, figs. 8).—While the importance of corn and other cereals in Hawaii has gradually waned, especially of late years, due to the losses occasioned by cutworms and other pests which have increased enormously with the depletion of the golden plover, it is thought that with the control of the cutworm the cultivation of corn will increase from year to year.

The insects mentioned as attacking corn include wireworms, cutworms, army worms, plant lice, leaf hoppers, defoliating caterpillars, earworms, and grain feeders. Two species of wireworms, namely, *Simodactylus cinnamomeus* and *Monocrepidius exsul*, have been observed commonly about corn plantations. The commoner species of cutworms attacking corn are *Agrotis ypsilon*, *A. crinigera*, *Cirphis unipuncta*, and *Spodoptera mauritia*. The most important natural enemies of cutworms are the tachinid flies *Frontina archippivora* and *Chætogædia monticola*, *Ichneumon koebeli*, and birds, especially the mynah, golden plover, and Chinese pheasant.

*Aphis maidis* is the species commonly found on corn, sorghum, and other cereals. "Aphids have many natural enemies, which tend to keep them in check and at times render them innocuous, notably the ladybird beetles *Coccinella repanda*, *C. abdominalis*, *Platyomus lividigaster*, *Scymnus notescens*, and *S. vividus*, the syrphid fly *Xanthogramma grandicornis*, the *Leucopis grandicornis* (Fam. Agromyzidae), and minute internal parasites—cynipids, chalcids, and braconids. A small black encyrtid, first noticed by Mr. Swezey in 1906,

is parasitic on *Aphis maidis*. It has been propagated by the writer for several months and is found to be highly efficient. In several lots examined, about 90 per cent of the plant lice had succumbed. . . .

"Corn is almost invariably attacked by a small leaf hopper, *Peregrinus maidis*, which is often so abundant on small plants as to effect a rapid withering of the plants and ultimately their complete destruction. The injury they do results from their draining the leaves of sap and slitting the midrib for the insertion of their eggs. The secretive habits of these leaf hoppers makes it very difficult to control them by artificial means." Little success has been had in the control of the leaf hopper with the use of sprays.

*Plusia chalcites* is especially injurious to young plants and *Amorbia emigratella*, a leaf roller, is found on plants in all stages of growth. Neither of these is considered particularly destructive to corn, since they are both very general feeders. *Batrachodra rileyi*, *Cryptoblabes aliena*, nitidulid beetle larvae, and the coffee bean weevil (*Araccrus fasciculatus*) commonly infest the ears of corn. The Angoumois grain moth and the rice weevil are said to be the most important enemies of stored grain.

**Insect notes**, H. A. BALLOU (*Agr. News [Barbados]*, 11 (1912), Nos. 270, pp. 282, 283, fig. 1; 271, p. 298, figs. 4).—The author reports observations made during the course of a trip to St. Kitts to study the insect enemies of sugar cane. The first paper discusses the injury to cane caused by *Termes flavipes*; the second discusses *Lachnosterna patruelis*, which occurs in considerable numbers, and a new root borer that is also quite common.

**Insects injurious to mushrooms**, C. H. POPENOE (*U. S. Dept. Agr., Bur. Ent. Circ.* 155, pp. 10, figs. 7).—The insects which more commonly attack mushrooms are maggots, mites, springtails, and sowbugs, the first mentioned being the most generally injurious. The mycetophilids *Sciara multisetta* and *S. agraria* and the phorid *Aphiocheta albidihalteris* are the species attracting the most attention as pests. In combating these maggots measures should be undertaken early in the season which will eliminate them from the mushroom house and prevent their subsequent entrance. They may be prevented from gaining entrance in manure from compost beds by heating to a temperature of 150° F. Fumigation with bisulphid of carbon just previous to planting the mushrooms is also productive of good results in destroying the maggots in the compost. Fumigation with tobacco is one of the best methods of destroying the adults.

The mushroom mite (*Tyroglyphus lintneri*) at times becomes so abundant in mushroom beds as to cover the surface of the compost and when present in such numbers is extremely destructive, feeding upon the mushrooms in all stages and penetrating the beds and destroying the mycelium. It is thought to be the cause in many cases of the failure of the spawn to grow. Besides the injury to the mycelium they cause damage to the fruiting bodies by eating into them, distorting or destroying the young growth. Under certain conditions the hypopus or migratory stage of this mite is produced. By means of sucking disks on the ventral surface of the body it attaches itself to insects and is transported to suitable breeding grounds in other localities, resulting in its appearance in localities far from previously infested beds. This mite may also obtain access to mushroom houses in infested compost or in spawn from infested houses. It is but little affected by fumigants suitable for the control of other mushroom pests, and the only measures applicable appear to be those of prevention. A predaceous mite belonging to the Gamasidæ frequently occurs in beds infested by the mushroom mite, feeding upon the latter and at times becoming so numerous as to entirely wipe out the pest.

Springtails (*Achoretus armatum*), which are present in almost all manure, where they feed on the decaying vegetation present, at times become quite injurious in mushroom houses. Mention is made of an outbreak of this pest in St. Louis, Mo., in which a bed 150 ft. in length was completely destroyed. Fumigation with hydrocyanic-acid gas at a strength of from 3 to 6 ounces to each 1,000 cu. ft. of air space will reduce their numbers without injuring the mycelium.

Two species of sowbugs, the greenhouse pillbug (*Armadillidium vulgare*) and dooryard sowbug (*Porellio levis*), may become the source of injury through their attacks on the caps or fruiting bodies of the mushrooms. The remedies mentioned include hand picking, pouring hot water along the cracks in the boards and in other places where the bugs may be concealed by day, and treatment with sulphur dioxide after the mushroom crop has been harvested and the compost removed. The plastering of the wet surface of cut potatoes with Paris green and laying them about on the beds is frequently successful in entirely ridding the houses of this pest. Certain crickets are also said to eat into the caps of the mushrooms, *Ceuthophilus pacificus* being mentioned as causing extensive injury to cultivated mushroom beds on the Pacific coast.

In summarizing the circular the author calls attention to the fact that the building should be as tight as possible with few outlets and screened with fine wire gauze.

The leopard moth and other insects injurious to shade trees in the vicinity of Boston. J. W. CHAPMAN (*Cambridge, Mass.: Harvard Univ., 1911, pp. 51, pls. 7*).—This paper, consisting of 3 parts, is based upon the studies conducted by the author in large part in the college yard of Harvard University.

Part 1 (pp. 6-29) is devoted to the leopard moth (*Zenzera pyrina*), its history, descriptions of its stages, life history and habits, economic importance, natural enemies, and suggestions in regard to control, with a bibliography of 31 titles. In combating the pest the author finds pruning and the cutting back of all infested parts to be very effective if the larvæ have not secured too great a hold on the trees and can not be reached individually with applications of carbon bisulphid or through the use of a wire. This is said to be most effective where the young larvæ are just beginning to show in the twigs and tips of small branches which wilt and die. They can be successfully reached by a pair of hooks such as are ordinarily used to remove the nests of the brown-tail moth. The author reports having taken 300 larvæ in this manner from a single elm. Bisulphid should be used, if possible, in all cases where the larvæ can not be reached by use of a wire. Other substances besides putty and grafting wax which may be used for stopping the holes are clay, coal tar, and in some instances a wooden plug driven into the hole and then sawed off close to the bark. The pupa, like the larva, can be destroyed by a wire, carbon bisulphid, or by simply closing the opening to the outside. Since the moths are attracted to light, a large number may be destroyed in this way.

In part 2 (pp. 30-40) the author describes and discusses the life history and habits, economic importance, etc., of the elm bark-beetle (*Eccoptagaster multistriata*), a preliminary account of which has been previously noted (*E. S. R.*, 23, p. 564). A bibliography of 22 titles is included.

In part 3 (pp. 41-45) brief notes are given on the carpenter moth (*Priorystus robinia*), elm-bark borer (*Hylesinus opaculus*), elm-leaf miner (*Kaliotenus ulmi*), elm-leaf beetle (*Galerucella luteola*), oyster-shell bark-louse, San José scale, white-marked tussock moth, elm-gall louse (*Colopha ulmicola*), woolly elm-tree louse (*Schizonura rileyi*), and brown-tail moth. In an appendix food plants of the leopard moth are listed by families.

**A manual of Philippine silk culture**, C. S. BANKS (*Manila: Bur. Sci., 1911, pp. 53, pls. 20*).—This work collates all the data accumulated during the 6 years that the Bureau of Science has propagated mulberry silkworms in the Philippine Islands, with a view to making them accessible to persons who desire to enter upon the commercial production of silk.

**Cutworms and army worms**, A. GIBSON (*Canada Dept. Agr., Div. Ent. Bul. 3, 1912, pp. 29, pl. 1, figs. 10*).—The first part of this bulletin deals with the nature of cutworm injuries, their life history, natural enemies, and preventive and remedial measures. The more common species of cutworms, namely, the red-backed cutworm (*Euroa ochrogaster*), the greasy or black cutworm, *Agrotis ypsilon*, the variegated cutworm (*Peridroma saucia*), the dark-sided cutworm (*E. messoria*), the white cutworm (*E. scandens*), the W-marked cutworm (*Noctua claudestina*), the spotted cutworm (*N. c-nigrum*), the glassy cutworm (*Hadenia devastatrix*), the yellow-headed cutworm (*H. arctica*), the clover cutworm (*Mamestra trifolii*), the dingy cutworm (*Feltia ducens*), the army worm (*Heliothia unipuncta*), and the black army worm (*N. fennica*) are then dealt with.

It is stated that many new and hitherto unpublished observations on the life histories of several species are recorded.

**The present outbreak of the fall army worm and recommendations for its control**, JAMES WILSON (*U. S. Dept. Agr., Office Sec. Circ. 40, pp. 2, fig. 1*).—This circular calls attention to the fact that *Laphygma frugiperda*, which has been present in unprecedented numbers from Louisiana and Arkansas eastward to the Atlantic Ocean and destroyed corn, cotton, sugar cane, rice, and other crops, can be best controlled by the application of arsenical poisons and the working of the soil.

**The present outbreak of the grass worm or fall army worm and recommendations for its control**, JAMES WILSON (*U. S. Dept. Agr., Office Sec. Circ. 40, rev., pp. 4, figs. 3*).—This is a revision of the circular noted above.

**Damage to sugar-cane juice by the moth stalk-borer (*Diatræa saccharalis*)**, D. L. VAN DINE (*Porto Rico Sugar Growers' Sta. Circ. 1, pp. 11*).—This circular deals with the effect of the borer injury on the sucrose content and purity of the juice of infested stalks, and reports comparative analyses of sound and borer-infested stalks of cane.

The author finds that "there is a direct loss in sugar and a decided reduction in the purity of the juice of cane infested by the moth stalk-borer. This loss in Porto Rico exceeded 670 lbs. of sugar per acre of cane in which the infestation was not apparent except upon examination, the yield averaging 41 tons of cane per acre and the stalks being normal and healthy in appearance. The loss increases in direct proportion to the number of joints of the cane stalks infested by the borer. There is more fiber and less juice in borer-infested cane. The actual weight of borer-infested cane is less than that of sound cane, and it is considered that the juice deteriorates more rapidly in infested cane when cane is allowed to stand without being crushed for any length of time after harvest."

**The "wilt disease," or "flacherie," of the gipsy moth**, W. REIFF (*Boston: State Forester, 1911, pp. 60, pls. 2, figs. 5*).—In part 1 (pp. 7-12) a brief account is given of caterpillar diseases in general. Part 2 (pp. 12-14) consists of a brief résumé of experiments with flacherie in 1909, an account of which has been previously noted from another source (*E. S. R., 22, p. 357*). Part 3 (pp. 14-52) reports the details of flacherie experiments conducted in 1910.

In the course of the work artificially developed flacherie was planted after the dying off of the breeding material had begun among the gipsy moth cater-

pillars in 12 separate localities. By taking the average of these results it was found that the total number of apparently living eggs had been decreased by introduction of the artificially developed flacherie to about 14 per cent.

The "experiments prove conclusively that flacherie has an injurious influence upon the prosperity of the gipsy moth caterpillars, this influence varying according to the manner and time of the appearance of the disease. There was no difference noticed in the progress of the wilt which broke out naturally and that of the artificially developed flacherie. The latter, however, is probably the more important factor, for with its help we may be able to introduce the disease among caterpillars of localities in which the wilt, perhaps, would not make its appearance naturally. . . . In selecting the localities in which the disease is to be introduced it is unimportant whether the caterpillars of the gipsy moth are present in large or small numbers. . . . Wherever the naturally as well as the artificially developed flacherie occurs the female caterpillars will always succumb to it more readily than the male."

**Studies on the wilt disease, or "flacherie" of the gipsy moth, R. W. GLASER and J. W. CHAPMAN** (*Science, n. ser., 36 (1912), No. 920, pp. 219-224*).—The authors, who have been engaged for several months in the study of the cause and nature of the wilt disease of gipsy moth caterpillars, have found polyhedral bodies clustered about their tracheæ analogous to those which have been found in the silkworm and nonne (*Lymantria monacha*) caterpillars. These bodies have a very high refractive index and resist all stains with the exception of iodine, in which they take on a uniform tint. By using a high magnification small wriggling organisms were observed in the fat cells and other cells at such times as the polyhedral bodies were clustered around the tracheæ. "These moving organisms were stained and found to be bacteria. From this time on we pursued the work along bacteriological lines and we believe have been able to demonstrate the etiological connection of these bacteria with the disease." They were found in great numbers in all parts of the intestine and in many caterpillars appeared to be in the act of perforating its walls. "The fat cells seem to be particularly liable to attack, which probably accounts for the saponified nature of the fat of sick caterpillars. . . . The organism in question is very small, having a diameter of only 0.51 to 0.85  $\mu$ . . . . It resembles the pneumococcus very closely except that it is motile, progressing in a gyrating manner. For this reason and because it seems to be an undescribed form, we have named it Gyrococcus."

In inoculation experiments 10 caterpillars out of 12 inoculated in the proleg succumbed to the disease. Two out of the 10 died in the pupal stage, while of the 2 surviving 1 was still in the pupal stage at the time of writing and 1 had emerged. Ten of the 12 inoculated in the dorsal vessel died and the remaining 2 were still pupæ. All of the deaths are said to have been typical of flacherie. The 2 lots used for feeding experiments all died without a single exception. In order to exclude the possibility of having inoculated an ultraviolet virus together with the Gyrococcus, a large number of caterpillars were prepared (blood tested) for inoculation and feeding with material passed through the Berkefeld filter. These all survived while those treated in the same manner with the unfiltered culture all died.

"The disease is probably spread in nature by the juices of disintegrated caterpillars flowing over the leaves which are later eaten by others. We have found Gyrococcus in the feces, and the fact that such excretions are washed over the leaves by rain seems to show that the disease may also be spread in this manner. What economic value the flacherie disease may have in combating the gipsy moth, we are not prepared at present to say. We have no

experimental evidence whatsoever that the disease may be air borne, as claimed by Mr. Reiff, although of course we do not wish to exclude such a possibility."

The paper concludes with a brief description of the new organism, *Gyrococcus flaccidifex* n. g. and n. sp.

Studies of the wipfelkrankheit of the nonne moth, K. ESCHERICH and M. MIYAJIMA (*Naturw. Ztschr. Forst u. Landw.*, 9 (1911), No. 9, pp. 381-402, figs. 6).—This article first briefly reviews the subject and discusses its diagnosis, then reports observations and experiments on the transmissibility of the virus of wilt disease in nun moth caterpillars, the course of the disease, and nature of the virus.

The Mycetophilidæ of North America, Part IV, O. A. JOHANSEN (*Maine Sta. Bul.* 200, pp. 57-146, pls. 7).—In this fourth paper (E. S. R., 27, p. 57) the species of the remaining genera of the subfamily Mycetophilinæ are characterized together with those of the subfamily Sciarinæ. "The members of the former so far as known injure mushrooms only; the latter constitute the most important group so far as the agriculturist is concerned.

"Though occasionally reported as injuring mushrooms the members of the Sciarinæ are not as a rule regarded as serious pests of the fleshy fungi, differing in this respect from the species of the other subfamilies. After partial decay of fungus growths, however, larvæ of *Sciara* are found in abundance, and it is this fact which, in some cases at least, has led observers and growers to attribute the destruction to these gnats when in all probability the injury was caused by species of *Mycetophila*, *Exechia*, or *Phorids*. On the other hand there is no lack of evidence of the harmful character of some species of *Sciarinæ* to seed corn, to potatoes, to wheat, and to the roots of other plants."

The biology of the cockchafer (*Terre Vaud.*, 3 (1911), No. 50, pp. 453-455. fig. 1; abs. in *Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 2, pp. 572-574).—This paper presents a brief account of work carried on by Decoppet, who has conducted studies at Farzin, in the Canton of Vaud, Switzerland, in a region where the farm and forest injuries caused by the pest are often very great, the roots and foliage of seedlings and trees (pines, spruces, larches, and silver firs), grasses, and some field crops being attacked.

The action of carbon disulphid on cockchafer larvæ and on the growth of some forest trees, DECOPPET (*Bul. Soc. Vaud. Sci. Nat.*, 5. ser., 48 (1912), No. 176, pp. XXXV, XXXVI; abs. in *Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 6, pp. 1456, 1457).—The author found that carbon disulphid at the rate of from 1 to 1½ oz. per square yard injected into 6 or more holes considerably diminished the injury caused by white grubs. In some of the experiments conducted the loss due to their attack in beds thus treated was reduced to 1 or 2 per cent, although it amounted to 20 per cent at the commencement and 80 per cent in untreated beds. Carbon disulphid also has a beneficial effect in stimulating the growth of vegetation.

The author concludes that the "application of carbon disulphid should become a regular practice in forest nurseries; it will not destroy all the white grubs in the soil, but will greatly reduce their number, thus permitting the plants to make new roots; and owing to the effect of the disulphid, the absorption of assimilable substances in the soil is increased, as is shown by the increased power of resistance possessed by the young trees. The disulphid must be injected into the soil as uniformly as possible, at the rate of 1 to 1½ oz. per square yard in 6 to 8 holes. Ground recently broken up should not be treated,

and some days should elapse after the application of the disulphid before plowing. Further, the soil must be neither too damp nor too dry. As the disulphid vapor sinks in the soil it must not be injected to a depth of over 6 in."

The destruction of the cockchafer in the forest nursery, DECOPPET (*Schweiz. Ztschr. Forstw.*, 63 (1912), No. 4, pp. 122-129, pls. 2, fig. 1).—This is a more detailed account of the investigations noted above, which have been under way since 1904.

The white grub of sugar cane in the island of Mauritius, A. VUILLET (*Sucr. Indig. et Colon.*, 80 (1912), No. 11, pp. 253-255).—This is a résumé of the present knowledge of the scarabæid *Phytalus smithi* and the means of combating it.

The control of the boll weevil, W. D. HUNTER (*U. S. Dept. Agr., Farmers' Bul.* 509, pp. 14).—The matter contained in this publication is extracted largely from Bulletin 114 of the Bureau of Entomology, previously noted (*E. S. R.*, 27, p. 562). It contains a brief outline of the methods which have been tested under various conditions and sums up the present available knowledge concerning the subject of control.

The honeybee, a guide to apiculture in Canada, C. G. HEWITT (*Canada Dept. Agr., Div. Ent. Bul.* 2, 1912, pp. 45, pls. 2, figs. 14).—This bulletin furnishes information for the practical beekeeper.

A revision of the Ichneumonidæ based on the collection in the British Museum, with descriptions of new genera and species, C. MORLEY (*London, 1912, pt. 1, pp. XI+88, pl. 1*).—The present work, which deals with the tribes Ophionides and Metopiides, is said to be the commencement of a revision of the family Ichneumonidae. Five genera and many species are described as new to science.

The ichneumon flies of America belonging to the tribe Ophionini, C. W. HOOKER (*Trans. Amer. Ent. Soc.*, 38 (1912), No. 1-2, pp. 176+176a-176c, pls. 3).—This revision of the Ophionini is based upon extensive museum and private collections, all but 4 of the types existing in America having been examined. Most of the species attack lepidopterous larvæ, including the army worm, cotton worm, zebra caterpillar, the large *Cecropia* larvæ, etc. *Ophion biforcolatus*, however, apparently confines itself to the larvæ of *Lachnosterna*. Synonymic lists are given of the genera and species. A number of species are described as new to science.

The clover mite (*Bryobia pratensis*), F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Circ.* 158, pp. 5, figs. 3).—This is a summarized account of the clover or brown mite. This pest attacks the leaves of clover, grasses, and fruit and other trees, feeding upon and often destroying them. In addition, during winter and spring it frequently swarms in dwellings, often crawling about in myriads over windows, furniture, pictures, curtains, etc. As a whole, throughout its known area of distribution, it is probably of more importance to the fruit grower than to the farmer. While east of the semiarid region it is found largely on clover and blue grass, it is at present largely an orchard pest west of about longitude 100°. "With the possible exception of Georgia, the pest seems to occur generally over the whole country, except perhaps in the Gulf States and the Dakotas, though just why it should not be found even there can not now be explained."

Caterpillars of *Tincola bisclivella*, one of the common clothes moths, have been observed to feed upon the eggs of this mite. A minute black lady beetle (*Scymnus punctum*) and lace-winged flies are also recorded as predaceous enemies.

Frequent reference is made to the investigations conducted by the Colorado Station, previously noted (*E. S. R.*, 23, p. 264).

List of insecticide dealers, C. W. WOODWORTH (*California Sta. Circ. 79, pp. 23*).—This circular lists the firms which have been licensed to sell insecticides and fungicides in California for the year ending June 30, 1913.

### FOODS—HUMAN NUTRITION.

Practical suggestions for the preparation of frozen and dried eggs, MARY E. PENNINGTON (*U. S. Dept. Agr., Bur. Chem. Circ. 98, pp. 12, pls. 3, fig. 1*).—A study of the fundamental facts underlying the problem of the preservation of eggs and egg products.

Examinations of eggs which had been commercially candled for breaking were made at different times at 6 different factories. The appearance, odor, and sometimes the taste of the egg when removed from the shell were added to the candler's description. Laboratory examinations were made to determine the number of bacteria present, and whether or not the organisms were of the colon type. The amount of nitrogen obtained from the eggs was analyzed according to the Folin aeration method.

With the exception of the eggs having green-colored whites, musty eggs, sour eggs, and eggs with a pronounced odor which the candler can not always distinguish, the eggs going to the breakers after careful handling were found to be, bacteriologically speaking, a clean, wholesome food. The eggs, however, were handled under very different conditions and the product varied greatly in bacterial content, although the percentage of loosely combined nitrogen did not vary to any great extent.

The bacterial content of egg products was proved to be largely a matter of handling, because there was a wide variation between the output of the different plants, and when eggs used by all of them were opened in a laboratory under aseptic conditions they were found to contain but few bacteria. Conversely, when they were opened in the laboratory according to methods prevailing in egg-breaking establishments, the product sometimes approximated closely that obtained in a commercial establishment. The fingers of the breaker were found to be one prolific source of trouble, as they are constantly wet. The dishes used were found to be another source of contamination, and in order to overcome this an improved egg-breaking outfit is illustrated and described. Suggestions are also offered for the construction of a suitable room for egg breaking, so that bacterial cleanliness may be preserved.

"Arrangements should be made for washing and sterilizing utensils outside of the breaking room. All eggs should be chilled at a temperature below 40° F. for 24 hours, as soon as received, candled in a chilled candling room (not above 65°), and transferred as soon as candled to the breakers. The liquid egg should go at once, preferably while the temperature is below 45°, in its ultimate containers, to a quick freezer. This necessitates a low-temperature room on the premises. . . . It is believed that, properly conducted, the freezing and drying of eggs is an industry which is economically desirable, as long as the centers of egg production and egg consumption are so widely separated, and as long as the poor handling methods bring to the concentrators of the producing sections such enormous numbers of eggs that are wholesome but not available for long hauls."

Oats in human nutrition, PLUCHET and NIVIOT (*Bul. Soc. Nat. Agr. France, 72 (1912), No. 7, pp. 586-591*).—Attention is called to the advantages which, in the authors' opinion, oats possess as food for man, and to experiments by Moreau of the French Army which appear to indicate that the addition of oats in some form or other to the ration increases the endurance of soldiers

Mention is made of a kind of bread made in Norway and Sweden of oatmeal mixed with ground pine bark.

**Rice** (*Cuba Mag.*, 4 (1912), No. 2, pp. 77-80).—A discussion of the use of rice, with a collection of recipes, a number of them for Cuban dishes.

**Bacterial changes in bread**, E. KAYSER (*Bul. Soc. Sci. Hyg. Aliment.*, 1 (1911), No. 3-4, pp. 349-357).—These experiments were made to ascertain the cause of viscosity and ropiness in bread and to discover a remedy for it.

It was found that the micro-organism (which is described) may be introduced in the yeast, the water, the milk, or the flour. To prevent the bread from spoiling the following remedies are suggested: Cleanliness, including washing the dough trough and other baking utensils with boiling acidulated water; addition of from 1 to 2 liters of vinegar to each 100 kg. of flour, or the addition of some form of lactic acid to the dough; in severe cases, changing the flour, the yeast, the milk, or using boiling water; and baking for a considerable time, 30 minutes being required for a 500-gm. loaf.

The cause and prevention of other defects in bread caused by micro-organisms and similar topics are discussed.

**Bacterial changes in bread**, E. KAYSER and H. DELAVAL (*Ann. Inst. Nat. Agron.*, 11 (1912), 2. ser., No. 1, pp. 143-153, fig. 1).—See above.

**A study of ropy bread**, ANNA W. WILLIAMS (*Biochem. Bul.*, 1 (1912), No. 4, pp. 529-534).—Experiments made to determine the cause of ropiness in bread and to devise preventive measures are reported.

The trouble was found to be due to the presence in the flour of a short, thick, sluggishly mobile, rod-bacillus having a capsule. The infected flour may also contain a coccus which produces a pink crumb, preceded by a characteristic odor of rope. The development of ropiness may be prevented by keeping the bread dry and at low temperature. Thin dough and underbaking favor the rapid development of ropiness, while buttermilk used in mixing the dough will tend to hinder the development.

**Increased cost of living and the use of food pastes**, E. JACQUET and G. ROVESTI (*Bul. Soc. Sci. Hyg. Aliment.*, 1 (1911), No. 3-4, pp. 358-370).—Increased use of food pastes such as macaroni is recommended as a means of reducing the cost of living. Analyses of these pastes are presented, and it is noted that the better grades contain a relatively high proportion of ash, fat, and cellulose, but less nitrogenous matter than the cheaper grades. Consideration is given to the selection of wheat, the drying of the paste, criteria of the quality of paste, kinds of paste, and trade statistics. Suggestions are given for increasing the use of this sort of food.

**Soy bean and condensed milk** (*Med. Rev. of Reviews*, 18 (1912), No. 8, p. 513).—In this summary of data a combination of the soy bean or its flour with sweetened condensed milk is recommended as an infant food as a substitute for fresh milk when the latter is not safe. The soy bean is valuable also in the treatment of diabetes on account of the absence of starch. Its flour is said to contain 44.6 per cent protein, 19.4 per cent fat, and 9.3 per cent cane sugar.

**The caloric estimation of percentage-mixtures of milk**, F. G. OPPENHEIMER (*Med. Rev. of Reviews*, 18 (1912), No. 9, p. 645).—Fraleys' method is cited which makes use of the formula  $2F + S + P \times 1\frac{1}{2} Q = C$ , in which  $F$  represents the percentage of fat,  $S$  of sugar,  $P$  of protein,  $Q$  the quantity in ounces, and  $C$  the caloric value.

**A nutrition investigation on the insoluble carbohydrates or marc of the apple**, E. C. SCHNEIDER (*Amer. Jour. Physiol.*, 30 (1912), No. 3, pp. 258-270).—The results of studies are reported of the composition of the apple and

apple marc, bacteria, enzymes, digestion, and utilization, and data reported by other investigators are summarized.

According to the author, 35.87 per cent of pentosan and 45.83 per cent of galactan were obtained from the marc by hydrolysis with hydrochloric acid. Intestinal bacteria destroyed the hemicelluloses of the marc and pectin, as well as the pentosan and galactan of the pectin, and did not form reducing sugars as an end product. Neither the marc nor its pectin was hydrolyzed by animal enzymes, malt diastase, or "taka" diastase. Weak solutions of hydrochloric acid split off from the marc pectin and reducing sugars. In digestion experiments made with human subjects from 79.1 to 84.5 per cent of the hemicelluloses of the marc was utilized or destroyed, probably by bacterial activity. Of the pentosan 88.69 per cent was digestible, and of the galactan 76.78 per cent.

**Official inspections** (*Maine Sta. Off. Insps.*, 37, pp. 13-24; 39, pp. 73-88; 40, pp. 89-100).—The first of these publications reports the results of the examination of a number of samples of carbonated beverages and ice cream; the second reports results of the examination of a number of miscellaneous food materials, and discusses sanitary food and related topics; and the third, the results of the examination of drugs.

**Food inspection decision** (*U. S. Dept. Agr., Food Insp. Decisions* 146, 147, pp. 1 each).—These decisions have to do with the use of saccharin in foods, and with absinth.

**School lunches and medical inspection**, I. S. WILE (*Med. Rev. of Reviews*, 18 (1912), No. 9, pp. 593-598; *Jour. Home Econ.*, 4 (1912), No. 4, pp. 345-352).—Arguments favoring the school lunch are presented in this summary of data, which includes the author's experience in school lunch work in New York City.

**Cost of living in Mexico**, P. E. HOLLAND and W. L. BONNEY (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 199, pp. 966-969).—Statistical data relating to the cost of living, and a description of the preparation of some Mexican dishes (tortillas, tamales, and enchiladas), are given.

**Food in Syria**, M. LABBÉ and J. ZIADE (*Bul. Soc. Sci. Hyg. Aliment.*, 1 (1911), No. 3-4, pp. 371-381).—A detailed description of the foods generally consumed in Syria is given.

The results of dietary studies are presented. In the case of a man weighing 85 kg. the daily food supplied from 138 to 147 gm. protein, the energy value being from 2,878 to 3,037 calories. In another case, with a man weighing 105 kg., the diet supplied about 228 gm. protein and 5,466 calories; and in a third case, with a man weighing 70 kg., 125 gm. protein and 3,848 calories.

According to the author's data, Syrian diet contains little meat and practically no alcohol. It contains large quantities of carbohydrates, and, they believe, supplies too much fat.

**The pathology of fat metabolism**, F. M. HANES (*Bul. Johns Hopkins Hosp.*, 23 (1912), No. 253, pp. 77-82; *abs. in Med. Rev. of Reviews*, 18 (1912), No. 6, p. 412).—"Fatty degeneration" is an inexact term for a variety of cell injuries accompanied with the appearance of fat.

Lipins (lipoids) of cells include not only neutral fats, fatty acids, and soaps, but also more complex substances which should be studied in connection with both normal and abnormal metabolism. Lipins are constant cell constituents, usually in invisible form, becoming visible with certain injuries to the cell, and forming fatty accumulations of lipins which the cell can not utilize and which are not the result of degenerative transformation of the cytoplasm into fat. These accumulations are physiological or pathological infiltrations. Glycerylester infiltration indicates injury to the containing cell, and cholesteryl-ester

infiltration indicates necrobiosis of neighboring cells. Chronic degenerative lesions produce cholesteryl-ester infiltration. Autolysis causes the invisible lipins of the cell to assume a visible form, differing from the lipins deposited in the cell during life. This process (myelinic decomposition) is not related to the process of fatty infiltration.

**The influence on the respiratory exchange of varying amounts of carbohydrate in the diet,** F. G. BENEDICT and H. L. HIGGINS (*Amer. Jour. Physiol.*, 30 (1912), No. 3, pp. 217-232, *dgm.* 1).—In these experiments diets supplying uniform amounts of protein and approximately the same number of calories, but with varying amounts of carbohydrates and fats, were fed to several individuals, and during 4 days measurements of the gaseous metabolism, particularly the respiratory quotient, were made.

It was found that with the diet unchanged on the preceding evening the respiratory exchange of any individual the next morning before eating is always the same. With normal subjects the same diet gives the same respiratory quotient the morning after a meal. A distinct relation was found between the supply of body carbohydrate (measured by the respiratory quotient after digestion has ceased) and the quantity of carbohydrate in the preceding diet. In men of sedentary habits even 600 gm. of carbohydrate daily for 4 days did not produce glycosuria.

**The influence upon metabolism of nonoxidizable material in the intestinal tract,** F. G. BENEDICT and L. E. EMMES (*Amer. Jour. Physiol.*, 30 (1912), No. 3, pp. 197-216).—These experiments were made in the attempt to determine whether the increase in metabolism (measured by oxygen consumption and carbon dioxide elimination) following ingestion of food is caused principally by the presence of oxidizable material in the blood or by muscular work involved in the process of digestion. Respiration apparatus previously described (E. S. R., 21, p. 665) was used.

In 6 experiments the subject took a dose of 15 gm. of sodium sulphate in 200 cc. of water. No considerable increase in either oxygen or carbon dioxide was noted, in spite of the intense peristalsis produced. Hence, the authors conclude, it is erroneous to cite the results of earlier experiments in support of the idea that intestinal movements have a very considerable effect upon total metabolism.

Seven experiments were made in which the subjects ingested considerable quantities of agar-agar, either dry or in the form of a jelly. None of this material, except a very little carbohydrate, is absorbed. No increased metabolism due to increased segmentation was noted, and the movement along the intestines of the material did not appear to require the expenditure of a measurable amount of energy. "It would therefore appear that the 'work of digestion,' in so far as either peristalsis or possibly the segmentation process is concerned, can not be of sufficient moment to play an important rôle or to explain in any degree the marked rise in metabolism so frequently noted after the ingestion of various food materials."

**The physico-chemical basis of striated-muscle contraction,** I. W. N. BERG (*Biochem. Bul.*, 1 (1912), No. 4, pp. 535-537).—This is a criticism of the Zuntz theory of muscle contraction.

**Studies of the animal body as a prime mover,** M. RINGELMANN (*Bul. Soc. Sci. Hyg. Aliment.*, 1 (1911), No. 3-4, pp. 337-348, *dgm.* 3).—This is an attempt to devise a method for measuring the power obtained from man or the lower animals, in the same way that an engineer determines the power of a prime mover. The analogy between the animate and inanimate machines is carried out in considerable detail, and formulas are presented for the measurement of

the force, speed, and power of the animate machine, just as there are formulas for determining these attributes in the case of an inanimate machine.

Experiments with cattle showed a relation between the effort of an animal and its weight, and between its effort and the dimensions of certain muscles. The speed of the animate motor is affected by the length of the limbs, by the angular velocity at which the various levers move in a vertical plane, and by the number of movements in a unit of time.

If  $f$  represents the mean effort,  $P$  the weight of the motor,  $n$  the ratio of  $f$  to  $P$ ,  $v$  the mean speed,  $H$  the height of the motor,  $n'$  the ratio of  $v$  to  $H$ , and  $fv$  the power of the motor,  $fv=mn'(PH)$ . Experiments demonstrate that  $f$  increases with  $P$ , while  $v$  increases to a maximum and then diminishes with increase in  $P$ . A graphic curve illustrates these relations. It may be possible to make the coefficients  $n$  and  $n'$  utilizable practically, their value depending on the age of the motor, or anatomical and physiological peculiarities, such as the dimensions of some parts of the animate machine, the frequency of respiratory movements or of the pulse, the temperature, etc.

In the experiments with cattle it was found that the maximum effort was about four times the mean, and the maximum speed about three times the mean.

If  $F$  equals the maximum effort,  $f$  the mean effort,  $a$  the ratio of  $f$  to  $F$ ,  $V$  the maximum speed,  $v$  the mean speed,  $b$  the ratio of  $v$  to  $V$ , and  $m$  the utilizable power of the animate machine,  $m=fv=(ab)FV$ . Since  $a$  and  $b$  appear to be constants for animals of the same species, age, etc., the product of the maximum speed and effort of an animal is the measure of its utilizable power.

Other analogies between animate and inanimate machines are presented.

A new calorimeter bomb with special advantages as to material of construction and method of operation, S. W. PARR (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 10, pp. 746-748, figs. 4).—The advantages of the calorimeter here described are: It is constructed of a new alloy of nickel, copper, tungsten, and chromium, with smaller amounts of manganese, aluminum, titanium, boron, and silicon, the alloy being very much cheaper than platinum, equally resistant to acids, and far less liable to fracture than enamel; rubber gaskets are substituted for the usual lead ones, permitting the securing of a perfect seal with the minimum of compression, this substitution being possible through the devising of a method of construction which prevents burning of the rubber; an improved form of valve for the admission of oxygen and release of gases after combustion; and a simple and efficient method of fastening the cap and sealing the cover.

Some tests on a new calorimeter bomb, R. H. JESSE, Jr. (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 10, pp. 748, 749).—An account is given of tests of the calorimeter bomb described above.

Tests with acids showed that the material of which the apparatus is constructed is sufficiently acid proof. Indirect proof indicates that the substitution of rubber gaskets for lead did not affect results, the amount of rubber exposed to the gases being a ring only 0.001 of an inch wide, and the gases being cooled by passing through a very narrow space between masses of cool metal before coming in contact with the rubber. No odor of burnt rubber was noted, and the constancy of the results was such as would hardly have been possible had any rubber at all been burnt. Tests with sugar showed that the apparatus is accurate within 0.07 per cent and tests with benzoic acid showed an accuracy within 0.04 per cent, which is as close an agreement as could be expected when temperatures are measured with a mercury thermometer, and which compares very favorably with the best work of electrical thermometers.

## ANIMAL PRODUCTION.

Digestion experiments with Texas hays and fodders, G. S. FRAPS (*Texas Sta. Bul. 147*, pp. 5-28).—The average composition of feeding stuffs used in the digestion experiments reported in this bulletin was as follows:

*Composition of Texas hays and fodders.*

Kind of feeding stuff.	Water.	Protein.	Ether extract.	Nitro- gen-free extract.	Crude fiber.	Ash.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Alfalfa hay.....	10.99	16.17	1.41	34.96	28.34	8.14
Bermuda hay.....	9.74	6.43	1.60	46.70	27.62	7.88
Bur clover.....	9.73	23.43	2.12	31.83	20.81	12.10
Buffalo grass.....	7.30	7.05	1.20	45.43	27.64	11.55
Corn shucks.....	7.75	3.20	.68	54.60	30.32	3.47
Cowpea hay.....	12.73	14.66	3.02	34.37	26.18	9.05
Guam grass.....	7.66	8.43	1.73	49.40	26.00	6.79
Johnson grass hay.....	8.69	7.44	1.68	42.44	27.40	12.36
Do.....	8.06	6.92	1.40	44.73	30.76	8.13
Kafir fodder.....	8.57	9.90	2.13	44.33	23.80	11.25
Millet.....	9.42	4.22	1.62	48.37	27.91	8.97
Oat hay.....	8.36	8.04	2.41	44.22	27.87	9.02
Peanut hay.....	8.60	13.56	8.56	39.02	22.82	7.44
Para grass.....	8.36	3.44	.91	46.74	33.80	7.10
Rice straw (Japan).....	6.68	3.92	1.24	37.82	33.26	17.10
Rice straw (Honduras).....	7.46	3.98	1.15	40.62	30.65	16.16
Sorghum hay.....	10.56	5.58	1.66	47.24	28.07	6.91
Vetch hay.....	6.76	15.00	1.58	37.53	27.28	11.87

The bur clover was cut when in bloom with most of the seed corn and dried in a large air-drying apparatus in the laboratory before chopping. It was free from dirt and was readily and completely eaten. Samples of bur clover were also collected at various stages of growth and gave the following analytical results:

*Composition of bur clover at different stages of growth.*

Stage of growth.	Date col- lected.	Water.	Protein.	Ether extract.	Nitro- gen-free extract.	Crude fiber.	Ash.	Water lost in air-dry- ing.
		<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Just in bloom.....	Mar. 23	3.02	27.10	4.18	40.49	14.12	11.09	83.8
Full bloom, part of seeds formed.....	Apr. 2	7.43	24.00	3.23	38.19	16.95	10.20	83.5
Most of seeds formed.....	Apr. 14	2.72	20.75	2.97	41.13	21.85	10.58	84.5
Still in bloom.....	Apr. 21	5.96	21.06	3.92	38.47	21.25	9.40	82.6
Part of leaves dy- ing, still blooms.....	Apr. 28	5.95	16.43	2.48	40.70	25.59	8.85	74.6
All seeds formed, some leaves dry, dropping off.....	May 7	6.90	15.70	2.58	36.76	30.58	7.48	58.8
Most of leaves and burs dropped off.....	May 20	7.05	11.01	1.84	33.46	38.25	8.39	56.7

The results of digestion experiments with sheep are given in the following table:

*Coefficient of digestibility of Texas hays and fodders.*

Kind of feeding stuff.	Protein.	Ether extract.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Alfalfa hay.....	73.8	4.9	65.0	45.4	58.0
Bermuda hay.....	48.9	46.9	50.2	50.8	28.0
Bur clover.....	80.7	5.4	75.9	64.2	62.6
Buffalo grass.....	53.2	35.5	58.0	58.4	24.3
Corn shucks.....	12.5	38.6	60.6	69.3	21.5
Cowpea hay.....	72.3	28.6	65.3	51.5	11.0
Guam grass.....	50.7	57.2	53.8	57.1	28.4
Johnson grass hay.....	41.0	52.2	52.3	65.9	15.9

Vetch hay.....	74.2	42.4	74.5	54.5	28.3

Fodder crops of the Punjab. J. M. DOUIE ([1912], pp. II+31+VII, pls. 2).—This describes methods of feeding cattle and discusses the food value of native and introduced plants used as fodder for live stock.

Statistical investigations into the utilization of fodder crops and capital by means of live stock in various districts in Germany, F. WATERSTADT (*Arch. Exakte Wirtschaftsforsch.*, 4 (1912), No. 1, pp. 88-128; *abs. in Internat. Inst. Agr.* [Rome], *Bul. Bur. Agr. Intcl. and Plant Diseases*, 3 (1912), No. 6, pp. 1412-1418).—This is a study of 443 farms, in which the results are arranged according to the Thünen system in the order of progressive decrease of the income derived from cattle and other domestic animals, in order to determine by such means their relation to the total receipts of the farm and the factors of production.

From the results, which are prepared in tabular form, there seems to be a correlation between the income produced by cattle and the net and gross income of the farm. Because of this it is urged that more live stock be kept, provided that the area under fodder crops is intensively cultivated so that the factors of production can be utilized to their fullest extent.

Handbook on grain and feeding stuff drying, D. MEYER (*Handbuch der Futtermittel und Getreidetrocknung*. Leipzig, 1912, pp. XII+294, pls. 5, figs. 111).—This describes the process, machinery, and other equipment required for drying grain, grass, clover, serradella, lupines, acorns, horse chestnuts, brewers' grains, yeast, distillery slop, and refuse from products of starch factories. The composition, digestibility, and other matters relating to the value of these materials as feeding stuffs are discussed.

Silage from turnip leaves, O. T. BJANES (*Norsk Landmandsblad*, 31 (1912), No. 34, pp. 451, 452, figs. 2).—Turnip-leaf silage, according to the author's experience, makes an excellent dairy feed when fed about 20 to 25 lbs. daily in connection with dry roughage and grain feeds. In order to obtain a good quality of silage it is important to ensile the leaves as soon as possible after the cutting, while they are still green and succulent. A small stack silo is described for making silage.

Feeding stuff inspection (*Maine Sta. Off. Insp.* 38, pp. 25-72).—Analyses are reported of cotton-seed meal, cotton-seed feed, gluten feed, linseed meal,

distillers' grains, red dog flour, wheat middlings, wheat bran, beef scrap, and mixed feeds. There is also a list of registered feeding stuffs and their guaranteed analysis.

**Commercial feeding stuffs of Pennsylvania in 1911, J. W. KELLOGG ET AL.** (*Penn. Dept. Agr. Bul.* 223, 1912, pp. 171).—Analyses are reported of cotton-seed meal; linseed meal; corn oil meal; distillers' grains; brewers' grains; malt sprouts; gluten feed; hominy feed; corn bran; corn flour; wheat, rye, and buckwheat middlings; wheat, rye, and animal by-products; wheat bran; wheat and rye offals; buckwheat feed; alfalfa meal; beet pulp; calf meals; and mixed, proprietary, condimental, and miscellaneous feeds.

**Feeding stuffs, R. H. CARTER and S. J. M. AULD** (*Jour. Southeast. Agr. Col. Wye*, 1911, No. 20, pp. 261-263).—Analyses are reported of a mixed cake, linseed cake, undecorticated cotton cake, rape nibs, Niger seed cake, meal, cod liver oil condiment, and molasses food.

**Condimental stock foods** (*Amer. Food Jour.*, 7 (1912), No. 8, pp. 16, 17).—An editorial which contains a discussion of the significance of the recent decision of the U. S. Supreme Court whereby States are authorized to enact and enforce laws relating to condimental stock feeds, and to charge a fee for their inspection.

**Analyses of some fats of the American buffalo (bison), A. H. SCHMIDT** (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 8, p. 592).—Analyses are reported of the fat of steers and of American bison, taken from different parts of the body.

The chief difference was in the kidney fats, the chemical constants of which are as follows: Buffalo, specific gravity 0.9346, free fatty acids 1.65 per cent, titer 52.2° C., iodine number 29.45, saponification number 199.3; steer, specific gravity 0.933, free fatty acids 0.6 per cent, titer 42.85° C., iodine number 48.86, and saponification number 196. The differences are thought by the author to be due to the difference in size of the kidneys, which in the bison are about one-half the size of the cattle kidneys.

**On the normal presence of manganese in animals, G. BERTRAND and F. MEDIGRECEANU** (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), Nos. 15, pp. 941-943; 22, pp. 1450-1452; *Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York]*, 15 (1912), Sect. VII, p. 35).—Traces of manganese were found in about 60 species of wild and domesticated animals, and it is therefore thought that its presence has some physiological significance and is not merely accidental, as is commonly supposed.

**The enzymes of the ovaries, W. LÖB and S. GUTMANN** (*Biochem. Ztschr.*, 41 (1912), No. 6, pp. 445-460; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 593, II, p. 783).—Catalase, diastase, lecithase, lipase, urease, nuclease, and proteolytic ferments of the trypsin and pepsin type were found in the ovaries of pigs. Peroxidase, invertase, lactase, glycolytic enzymes, desamidase, and tyrosinase were not detected.

**The behavior of fat-soluble dyes and stained fat in the animal organism, L. B. MENDEL and AMY L. DANIELS** (*Jour. Biol. Chem.*, 13 (1912), No. 1, pp. 71-95).—The work of other investigators on this topic is reviewed and experiments in feeding dyes to rats, cats, guinea pigs, pigeons, hens, frogs, a cow, and a goat are reported. The dyes used were Sudan III, Biebrich scarlet, indophenol, oil-soluble green, oil orange, blue base, Dandelion Brand butter color, and annatto.

The results, which in general are comparable to those previously noted from other sources, are summarized as follows: "Some of the fat-soluble dyes, introduced into the organism by various paths, are deposited in the adipose

tissues and bone marrow. The renal and nervous tissues are free from the stain, even when the fatty tissues are deeply colored. Muscle probably does not take up the dye. It is seldom found in the liver, because the fat-soluble dyes, which are insoluble in water, dissolve readily in the bile and are excreted thereby into the intestine from which they can be reabsorbed.

"The fat-soluble dyes may enter the organism from the alimentary tract through the lymphatics, in solution in fat; or by the portal circulation, dissolved in reabsorbed bile. They do not pass beyond the liver unless fat is present to transport them. Then they may be found in the blood, which is rarely free from the dye in a normally fed animal that has once been stained. A cycle between intestine, bile, and blood becomes established. No elimination of the dyes occurs through the kidneys, except when an alimentary lipuria arises (in rabbits and rats).

"Contrary to the assertion of others, the stained fat is no less available to the organism than the unstained. In cases conducive to fat transport—in starvation, phosphorus and phlorhizin poisoning—stained fat migrates from the stained depots to the blood and the liver cells. Here the dye is separated and secreted into the bile, so that the liver, though having a high content of fat, may be free from the dye. Stained fat does not traverse the placenta. The blood of the fetus and the fat of young born of Sudan-stained mothers are free from dye.

"The excretion of Sudan III and Biebrich scarlet in milk, when they are given with food fat, suggests that the latter may pass directly into the mammary secretion. With cats and rats the results are striking, but the dye excretion in milk ceases when the stained food is no longer fed. In guinea pigs and goats the secretion of dye in the milk is positive; in the cow it has not yet been demonstrated. The variation in the outcome in the different species may be due to variations in the relative abundance in the dietaries of fat necessary for the absorption and transport of the dye. This explanation is emphasized by the observation that those animals (cats, rats, hens, pigeons) for which fat enters more largely into the diet, become stained more easily or speedily than animals which are accustomed to ingest relatively smaller amounts of fat."

**The misuse of the term "melanin,"** R. A. GORTNER (*Science, n. ser., 36 (1912), No. 915, pp. 52, 53*).—The author suggests that we substitute for melanin and melanin nitrogen of protein hydrolysis the terms proposed by Osborne, humin or humin nitrogen, and reserve the term melanin for those dark pigments which occur normally or pathologically in the animal body, skin, hair, or feathers.

**The case of generalized melanosis in fowls,** LEWIN (*Ztschr. Veterinärk., 22 (1910), No. 10, pp. 455, 456; abs. in Berlin. Tierärztl. Wchnschr., 28 (1912), No. 31, p. 567*).—A brief description of a cock in which melanotic pigment was present in the muscles, bones, and other internal tissue as well as in epidermal structures.

**The present status of the genetics problem,** W. J. SPILLMAN (*Science, n. ser., 35 (1912), No. 907, pp. 757-767*).—The author briefly discusses some of the principal results which have been accomplished by the different methods of studying heredity. Some suggestions for future work are offered.

**Negative results of in-and-in breeding among wild animals,** W. T. HORNADAY (*Proc. Internat. Zool. Cong., 7 (1907), pp. 162-164*).—The author believes that the evil effects supposed to be due to in-and-in breeding when practiced among domesticated animals do not occur in the case of wild animals, provided they are given free range, proper protection, and abundant food. These

views are based on the results accomplished in 45 years' breeding of red deer in New Zealand and 15 years' breeding of fallow deer on the Island of Lambay.

**Live-stock breeding in Hungary, J. ROSTAFINSKI** (*Die Tierzucht Ungarns. Vienna and Leipsic, 1912, pp. IX+178, pls. 40, figs. 56; abs. in Österr. Molk. Ztg., 19 (1912), No. 16, p. 249*).—A treatise which discusses the conditions of the live-stock industry in Hungary and describes methods of breeding, feeding, and managing horses, cattle, sheep, and swine.

**Statistical data on our European meat trade, J. E. RICHELET** (*Bol. Min. Agr. [Buenos Aires], 14 (1912), No. 2, pp. 167-197*).—This contains data on the production and export of meat from Argentina.

**The origin and use of the herd book, with special reference to cow-testing associations and judging live stock, W. LÜKEN** (*Kühn Arch., 1 (1911), pt. 2, pp. 253-319*).—This article discusses the substantial features of herd books as a means for improving live stock. Detailed measurements are also given of zebus, yaks, gayals, and bantengs, and of crosses of zebus and gayals with common breeds of cattle.

**Native and grade cattle breeding, J. M. SCOTT** (*Florida Sta. Bul. 110, pp. 59-72, figs. 9*).—Native cows were bred to Hereford, Shorthorn, and native bulls and kept on the same range until the calves were weaned. After weaning time the calves were all kept on the same pasture in summer, but in the winter were given the range of a velvet-bean and Japanese-cane field. The average birth weights were as follows: Five grade Herefords, 47.9 lbs.; 4 grade Shorthorns, 56 lbs.; and 3 natives, 48.6 lbs. At weaning time, when the calves were 7½ months old, the weights were for the grade Herefords 351.6 lbs., grade Shorthorns 342.5 lbs., and natives 305 lbs. The average weights of 2 animals in each lot at 1 year of age were, grade Herefords 405 lbs. and grade Shorthorns and natives 447.5 lbs.

When weighing about 700 lbs. these 6 animals were put in a small yard and fed for 90 days a ration of shelled corn, cotton-seed meal, and Japanese cane. The average daily gains per head and day were 1.25 lbs. for the grade Herefords, 1.89 lbs. for the grade Shorthorns, and 1.78 lbs. for the natives.

The author discusses beef production in Florida and advocates better winter feeding of native cattle and the selling of calves at weaning time.

**The organization of cattle breeding in Kamerun** (*Deut. Kolon. Bl., 33 (1912), No. 6, pp. 253-260; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases, 3 (1912), No. 6, pp. 1366, 1367*).—An account of breeding operations by the German government in introducing zebus and the Allgau breed to cross with the native cattle of Kamerun.

**Investigations on the rutting of cattle, E. WEBER** (*Untersuchungen über die Brunst des Rindes. Abhandl., K. Sächs. Tierärztl. Hochsch. Dresden, 1911, pp. 67*).—Previously noted from another source (*E. S. R., 26, p. 367*).

**Cattle feeding, W. HAWK** (*Cornwall County Council Agr. Expts. 1911, pp. 1-46*).—In a feeding test with 15 steers the addition of 28 lbs. of mangels to a daily ration of 2 lbs. decorticated cotton-seed cake, 2 lbs. corn meal, and second-rate hay increased the daily gains per head from 1.25 lbs. to 1.83 lbs., and the addition of 56 lbs. of mangels increased the daily gains to 1.86 lbs. Two steers fed mangels and good hay ad libitum, with 6 lbs. corn meal, gained 1.61 lbs. each daily for 2 months against 1.45 lbs. for 4 steers on good pasture and hay ad libitum with 6 lbs. corn meal. Analyses are given of a large number of samples of mangels.

Four heifers fed daily 2 lbs. soy-bean cake, 2 lbs. undecorticated cotton-seed cake, and 2 lbs. corn meal each gained 2.64 lbs. per head and day for 18 weeks against corresponding gains of 2.46 lbs. for 3 heifers fed 3 lbs. linseed meal and 3 lbs. decorticated cotton-seed cake. Three heifers fed 3 lbs. soy-bean cake and

3 lbs. undecorticated cotton-seed cake gained 2.5 lbs. per head and day for 18 weeks against a corresponding gain of 2.54 lbs. for 3 heifers fed 6 lbs. linseed meal. It is stated as a result of feeding experiments with young cattle that if they could be kept in a thriving instead of a stationary condition all winter the percentage of deaths during the spring would be enormously diminished.

[Dried beet pulp for fattening cattle], J. MACKINTOSH (*Jour. Southeast. Agr. Col. Wyc.*, 1911, No. 20, pp. 31-38).—In tests with steers 1 lb. of beet slices was found to be equivalent to about 8 lbs. of mangels, but it is stated that it is inadvisable to feed more than 7 lbs. of the pulp per head per day.

Fattening calves in Alabama, D. T. GRAY and W. F. WARD (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.*, 117, pp. 40, pls. 3).—The data reported in this bulletin have been previously abstracted from another source (*E. S. R.*, 27, p. 372).

Sheep feeding and farm management, D. H. DOANE (*Boston, New York, and London*, 1912, pp. XII+128, pls. 2, figs. 38).—A practical work on modern and profitable methods for buying, feeding, and marketing sheep, based on a study of actual farm practices on farms in different sections of the United States.

Horse breeding in Tunis, P. DIFLOTH (*Vie Agr. et Rurale*, 2 (1912), No. 8, pp. 193-197; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 4, pp. 967, 968).—This discusses the measures by which horses have been improved in Tunis since the French occupation in 1881.

Investigations into the growth of the hoof of horses, C. SCHULZE (*Monatsh. Prakt. Tierheilk.*, 22 (1912), No. 1-2, pp. 64-85; *abs. in Deut. Landw. Presse*, 39 (1912), No. 7, pp. 67, 68; *Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 3, pp. 734, 735).—The following results were obtained as a result of measuring the growth on 800 hoofs:

“The growth of the wall of the hoof averages 7.66 mm. per month. Unshod hoofs grow 8.6 mm. on the average per month, and shod hoofs only 6.73 mm. . . .

“The fore and hind hoofs grow at about the same rate, but the rate of growth of the different hoofs is seldom quite uniform. The hoof growth around the coronet is uniform in 90.6 per cent of all hoofs and irregular in 9.4 per cent. Irregular growth rarely occurs with regular shapes of hoof.

“When unshod hoofs are shod, there is an arrest of growth. Good care of the hoofs and good shoeing, especially that method of shoeing by which the hoof approximates more to natural conditions (seated shoes and half shoes), may reduce this injurious effect.

“The hoofs of horses aged from 5 to 10 years have on the average a monthly growth of 0.29 mm. faster than the hoofs of horses aged from 11 to 19.

“The color of the hoof has no relationship to its rate of growth. The duration or kind of work does not affect the rapidity of hoof growth to any ascertainable extent.

“In foundered hoofs the heel grows more rapidly than the toe and quarters. In hoofs shod with bar shoes the toes grow from 2 to 5 mm. more per month than the remaining wall sections. Injuries to the hoof coronet give rise to an additional growth up to 7 mm. per month in the corresponding part of the wall.

“Single dressings with cantharis ointment or cauterization of points on the coronet usually result in an increased growth of 3 mm. in the wall in the month following. A better result is obtained by frequently repeated dressings with ointment, but there is no specific capable of permanently increasing the horn production.

“Hoofs in which the volar or plantar nerves are severed grow on the average 2.5 mm. per month more than sound hoofs.

"General diseases as a rule lead to no arrest of hoof growth; indeed there is often an enhanced growth after recovery from a disease. The hoof horn, however, becomes dull when the animal is ill and shows a deficiency in moisture and elasticity."

**Contribution to the study of the dentition of the Equidæ, A. VEITH** (*Arch. Naturgesch.*, 78 (1912), *Abt. A*, No. 5, pp. 1-33, pls. 2).—A discussion of the character and succession of teeth in horses, zebras, and extinct equine types.

**Ostriches [and stallions] from the Sudan** (*Agr. Jour. Union So. Africa*, 3 (1912), No. 6, pp. 807-813).—A brief report of an expedition sent by the Union Government of South Africa to secure, if possible, some ostriches from the northern sections of the continent, where there is believed to be a special type from which the best feather producers of the South African birds have descended.

The feathers which could be obtained from birds east of Lake Chad were very thin, much like the feathers of the wild birds of South Africa. In northern Nigeria 140 birds were obtained and taken to Cape Town. The peculiarities of these birds were dense, healthy, short feathers, red skins, bald heads, and eggs larger than the South African ostriches, but unpocketed and a thin shell.

There is a note concerning 2 Asben stallions obtained from the Tuarek tribe, a breed which is considered by these people to be superior to the Arabian horses and which has been kept pure for many centuries.

**Poultry keeping as an industry for farmers and cottagers, E. BROWN** (*London, 1912*, 8. ed., pp. VI+206, pl. 1, figs. 110).—Some of the chapters in this book have been rewritten since the last edition, and much new matter has been incorporated embodying the more recent results of practical experience in poultry keeping.

**Fleshing chickens for market, W. A. WILSON** (*Saskatchewan Dept. Agr. Bul.* 25, 1911, pp. 29, figs. 15; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases*, 3 (1912), No. 3, pp. 7½, 7¾).—The average cost of fattening poultry in experiments carried out in the years 1907 to 1910 was 5.98 cts. per pound dressed weight, and the selling price 18.74 cts. per pound dressed weight. The average dressed weight per bird was 3.23 lbs. The methods of feeding are given.

**A new process of preserving eggs** (*Sci. Amer. Sup.*, 74 (1912), No. 1909, p. 76, figs. 4).—This describes the process invented by M. Lescardé in which the eggs are placed in a specially constructed metal box and carbon-dioxid and nitrogen gas used as sterilizing agents.

"When the box is filled with eggs, a small amount of chlorid of calcium is put in to absorb the greater part of the moisture of the air, and then the cover is soldered on, leaving a small hole in the top for the circulation of air or gas. The boxes are then ready to be taken to the sterilizer, which consists of a large cylindrical tank. . . . The boxes are stacked upon roller trucks, which are then run upon rails to the tank, a considerable number being treated at a time. The cylinder has a tight closing door, and resembles an injecting cylinder for treating railroad ties. The tank is first of all exhausted to extract the gases or air from the air pocket of the eggs and also the gases dissolved in the albumin. After this has been done, carbonic-acid gas is sent into the apparatus from steel bottles containing compressed or liquefied gas. As the gas which leaves the bottles becomes very cold owing to its expansion it is warmed somewhat to prevent cracking of the eggshells. For this purpose the gas is run through a worm tube placed in a tank of warm water. The pressure in the tank is observed by means of a gauge. After admitting a certain amount, the gas is shut off for a time, while it continues to be absorbed by the albumin of the eggs. Fresh gas is then let in when the pressure is seen to fall, and

this is kept up until the eggs absorb no more gas. When the proper point in this operation is reached the carbonic-acid gas is shut off, and a portion of it is then again extracted by pumping, to be replaced by a certain amount of nitrogen fed from compressed gas cylinders. The eggs are then ready to be removed from the tank, and the trucks are rolled out, after which the workmen soldier up the small inlet opening. As the pressure in the box is above atmospheric, there is no danger of air leaking in."

\* **The Canada grouse (*Dendragapus canadensis*) in captivity; its food, habits, etc.**, W. L. BISHOP (*Proc. and Trans. Nova Scotian Inst. Sci.*, 13 (1911-12), No. 2, pp. 150-153).—This account is based on several years' experience in keeping Canada grouse or "spruce partridge" in an inclosure.

**International Association of Instructors and Investigators in Poultry Husbandry** (*Proc. Internat. Assoc. Instr. and Invest. Poultry Husbandry*, 1 (1908-1910), pp. 164, pls. 4, figs. 5).—This contains the proceedings of the association for 1908, 1909, and 1910. The following are among the more important papers which have not been previously noted from other sources: *The Field of Research in Poultry Husbandry*, by H. Atwood; *The Present Status of Investigation of the Problems of Poultry Culture*, by P. B. Hadley; *Profitable Lines of Investigation in Poultry Diseases*, by G. B. Morse; *Present Condition of Experimental Work in Feeding*, by R. R. Slocum; *Comparison of Poultry Keeping in Europe, United States, and Canada*, by W. Brown; *An Outline for a Course of Study in Poultry Husbandry*, by J. E. Rice; *Study of Feeds and Methods of Instruction in Feeding*, by W. G. Krum; *Instruction in Feeding Poultry*, by C. A. Rogers; *Poultry Pathology. Its Place in the Curriculum*, by G. B. Morse; *Teaching by Farm Trains and Educational Exhibits at Fairs*, by W. A. Brown; and *Teaching by Lectures, Recitations, and Reference Reading*, by W. A. Lippincott. Appended is a bibliography of about 1,000 titles.

## DAIRY FARMING—DAIRYING.

**The relation between form and function in dairy cattle and the outer milk signs of cows**, W. GAUDE (*Arch. Deut. Gesell. Züchtungs-k.*, 1911, No. 7, pp. X+799, tables 18).—The author reports measurements and other data concerning 715 dairy cows in tabular form. The conclusion is drawn that external measurements do not furnish a guide to the milk-producing capacity of the dairy cow, but, as Rodewald has shown for the data reported by Schmidt and Kronacher (*E. S. R.*, 21, p. 778), this finding may be due to the method of tabulation employed by the author.

**Conformation and milk production** (*Österr. Molk. Ztg.*, 19 (1912), No. 1, pp. 1, 2).—A discussion of the views of Gaudé, noted above, and others who have written on the subject of correlation between form and function of dairy cows.

[**The relation between conformation and milk production**], J. H. W. T. REIMERS (*Cultura*, 24 (1912), Nos. 281, pp. 21-34; 282, pp. 78-91; 283, pp. 113-121; 284, pp. 144-157; 285, pp. 184-194).—Measurements of dairy cows are given, and the correlation between form and function is discussed.

**Progress made in the improvement of the Norrland mountain breed of cattle during the last two decades**, E. O. ARENANDER (*K. Landtbr. Akad. Handl. och Tidskr.*, 51 (1912), No. 5, pp. 336-361, figs. 11).—This is a discussion of the various agencies that have been brought to bear on the recent improvement of this Swedish breed, and the yields of 3 herds during 1904-1908 are given as an illustration of the progress made. One of these increased in production from 2,409.6 to 2,597.4 kg. of milk per head, and from 93.19 to 118.07 kg. butter fat, the average Swedish feed units (each equal to 2 Danish

feed units) eaten in 1904 being 1.244, and in 1908 1.367. A similar increased production was obtained in other herds. The maximum yield of a cow for the year in these herds was 4,195 kg. milk, containing 165.53 kg. fat; the feed units eaten, 1,800. The increase in production has come through systematic breeding, by the use of pure-bred bulls of proved dairy capacity, and through improved methods of feeding and caring for the cattle. In the author's opinion the old Swedish mountain breed is splendidly adapted to, and in some ways is unexcelled for, Norrland, and should be retained and further improved.

**Experiments in milking cows two and three times a day, N. O. HOFMAN-BANG ET AL.** (*Ber. K. Vet. og Landbohøjskoles Lab. Landøkonom. Forsøg [Copenhagen]*, 78 (1912), pp. 50).—In milking trials on 4 different estates, involving 172 cows that averaged from 13 to 14 kg. of milk per day, milking 3 times a day produced an average increase of 0.8 kg. per head and day. The fat content was not appreciably affected, but where the cows were not fed heavily there was a slight loss in body weight. These trials did not furnish any evidence as to the possible influence that frequent milking of heifers might have on the development of the milking capacity of the mature cow.

**Frees cottagers' cow club** (*Jour. Bd. Agr. [London]*, 19 (1912), No. 5, pp. 388-392).—A society composed of owners of small farms in Shropshire, England, who have since 1838 run a successful system of live-stock insurance, under which the members in return for a payment of 4s. 2d. per cow per annum receive the value up to £12 for every insured cow that dies of disease or accident. A reserve fund of £1,040 has accumulated, which secures them against having to meet heavy losses.

**The dairy industry in western Siberia and the possibilities of its extension, HOLLMANN** (*Mitt. Deut. Landw. Gesell.*, 27 (1912), Nos. 12, pp. 182-186; 13, pp. 197, 198; 14, pp. 211-214; *abs. in Internat. Inst. Agr. [Rome]. Bul. Bur. Agr. Intcl. and Plant Diseases*, 3 (1912), No. 6, pp. 1428-1431).—A general statistical account of the development of the dairy industry in Siberia since the first dairy was established at Kurgan in 1894.

**Journal of the British Dairy Farmers' Association, 1912** (*Jour. Brit. Dairy Farmers' Assoc.*, 26 (1912), pp. 288, figs. 16).—This contains reports of the International Dairy Congress at Stockholm, 1911, the dairy show of the British Farmers' Association, 1911, milk trials and butter tests, and other matters relating to the dairy industry in Great Britain. Among the papers on special topics are the following: The Dairy Industry in the Netherlands, by J. J. L. Van Rijn; Milk Records, by J. Mesdag; Fighting Contagious Diseases of Animals in the Netherlands, by J. Poels; Cooperative Bacon Curing, by L. M. Douglas; The Letting of Dairies, a West Country Custom, by J. H. Burton; The Dairy Conference in Holland, by F. J. Lloyd; and Rearing and Preparing Poultry for Market, by S. C. Sharpe.

**Report of the dairy and cold-storage commissioner, J. A. RUDDICK ET AL.** (*Rpt. Dairy and Cold Storage Comr. Canada, 1912*, pp. 150, pls. 6).—This contains records of dairy herds, data on the cost of milk production, trade in milk and milk products, the temperature of creamery butter at shipping stations, cow testing associations, and brief reports on care and handling of cream for butter making.

**Report on the activities of the dairy institute at Proskau, KLEIN** (*Ber. Milchw. Inst. Proskau, 1911-12*, pp. 17).—This reports analyses of milk, trials of dairy apparatus, and other work on related topics.

**The cost of milk production in Hungary, E. KOEFER** (*Indus. Lait. [Paris]*, 37 (1912), No. 35, pp. 594-598).—Figures are given showing the mean annual cost of milk production in Hungary from cows producing an average of 6 liters of milk daily to be 14.57 fillers per liter (about 3 cts. per quart).

The milk supply of Genoa, E. BERTARELLI (*Chacaras e Quintacs*, 5 (1912), No. 2, pp. 4-9; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Discusst.*, 3 (1912), No. 4, pp. 1914, 1015).—Since the formation of an association of the milk producers that send milk to Genoa the quality of the milk has improved and the consumption greatly increased. The retail price is about 31 cts. per gallon, and the expense per gallon as follows: Cost of milk 16.4 cts., freight to Genoa 1.7 cts., cartage from railway to town 0.9 ct., town duty 3.5 cts., handling and storing at Genoa 1.7 cts., sale and general expense 3.5 cts., and return of empties 0.9 ct.

Studies of pure milk, C. GRANVIGNE and G. CASSEZ (*Separate from Compt. Rend. Assoc. Franç. Adv. Sci.*, 1911, pp. 14).—Analyses are reported of mixed milks and butter made from samples thereof.

The factors affecting the fat content of milk, A. MALLÈVRE (*Bul. Soc. Sci. Hyg. Aliment.*, 1 (1911), No. 1-2, pp. 52-62).—A general discussion of the influence of breed, feed, and other factors which affect the percentage of fat in milk.

Changes in the composition of the milk of the cow on different diets, K. HELLE ET AL. (*Ztschr. Biol.*, 58 (1912), No. 8-11, pp. 355-374; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 598, II, p. 786).—The effect of various diets on the composition of milk was slight. The protein, sugar, and ash remained very constant. The amount of fat, solids-not-fat, and the fuel value varied more or less from day to day. Data are also reported on the specific gravity of the milk, the specific gravity of the serum, freezing point, osmotic pressure, refraction of the serum, and electrical conductivity.

The iron content of goat's milk, M. STAFFORD (*Ztschr. Kinderheilk., Orig.*, 4 (1912), No. 2, pp. 168-170; *abs. in Zentbl. Expt. Med.*, 2 (1912), No. 4, p. 149).—The author found from 1.27 to 2.63 mg. of iron in 1 liter of goat's milk.

Arsenic in milk, I. McCRAE (*Agr. Jour. Union So. Africa*, 3 (1912), No. 6, pp. 842, 843).—Samples of milk were taken from cows which had been habituated to a weekly arsenical dip for many years.

By the Reinsch process, which is capable of detecting 0.0001 grain of arsenic, no indication of the presence of this element could be obtained when working on 100 cc. Arsenic was present in some samples, as indicated by the Marsh process, but there could not have been enough in any case to have any toxic effect. Other samples were entirely free from arsenic. This indicates that the arsenic is not absorbed by the animal and secreted in the milk, and wherever traces of arsenic have been present it has probably been due to accidental contamination during the process of milking.

It was found that distilled water free from arsenic, after standing in a new washed glass bottle for 14 days, absorbed from the glass enough arsenic to be revealed by the Marsh test. Therefore, the danger to the consumer from milk may be less when cows are dipped in arsenical solutions than when milk is kept in glass bottles, but both dangers are considered negligible.

Preservation of milk samples for analysis [with potassium bichromate], X. ROCQUES (*Ann. Falsif.*, 5 (1912), No. 45, pp. 338-342; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 15, p. 742).—Studies of milk samples preserved with potassium bichromate in accordance with the French law (1 gm. per liter of milk) showed the necessity of adding the bichromate to the milk as soon as possible, because of the marked reducing action of lactic acid. If changes have already taken place before the bichromate is added, analysis should be performed as soon as possible. After keeping for some time lactic acid entirely reduces the bichromate present and so destroys the antiseptic action.

Shall we abandon fresh milk? R. E. WOOD (*Amer. Food Jour.*, 7 (1912), No. 8, pp. 1-4, figs. 3).—This discusses the value of pasteurizing and inspection of milk as safeguards against milk-borne epidemics of disease. Sterilized and evaporated milk delivered to the consumer in hermetically sealed packages is advocated as the only milk for those who seek an absolutely hygienic product.

Market milk regulation (*N. Y. Produce Rev. and Amer. Cream.*, 34 (1912), No. 7, pp. 330-333).—This gives a classification of milk and cream, definitions of bacteriological and chemical standards, and rules for producing, handling, and distributing milk, suggested by the New York Milk Committee.

That milk control, J. H. MONRAD (*N. Y. Produce Rev. and Amer. Cream.*, 34 (1912), No. 12, p. 556).—A criticism of the recommendations of the New York Milk Committee, noted above.

Milk control regulations, C. E. NORTH (*N. Y. Produce Rev. and Amer. Cream.*, 34 (1912), No. 19, pp. 816, 817).—A discussion of the report of the milk commission, noted above.

A lawyer's views on milk standards and regulations, W. J. CARLIN (*Cream, and Milk Plant Mo.*, 1 (1912), No. 1, pp. 9-11).—The author suggests efficient state inspection of dairies as a solution of the difficulties connected with milk inspection, and states that reasonableness is the test by which standards and regulations must eventually stand or fall.

Milk and cream regulations (*Brit. Food Jour.*, 14 (1912), No. 164, pp. 146-149).—These regulations of the Local Government Board of England and Wales, issued in 1912, prohibit the use of preservatives in market milk or the addition of any thickening substance to cream. Boric acid, borax, or hydrogen peroxid may be added to cream containing more than 35 per cent fat under certain restrictions.

The score-card system of dairy inspection, G. M. WHITAKER (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 199, pp. 32).—A revision of Circular 139, previously noted (*E. S. R.*, 20, p. 1073).

A simple butter color standard, S. H. AYERS (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 200, pp. 3, fig. 1).—This circular advocates as a standard for comparing color for butter fat the use of a graduated series of solutions of bichromate of potash of varying strength, so arranged as to give a range of color from a light to a dark yellow. Each shade is given a numerical value. The method of using the standard is given in detail.

In regard to the consistency of the cheese mass during the manufacture of Edam cheese, W. VAN DAM (*Centbl. Bakt. [etc.]*, 2. Abt., 32 (1911), No. 1-2, pp. 7-40, figs. 3; *Verlag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands]*, 1911, No. 10, pp. 5-49, figs. 3; *Rev. Gén. Lait*, 9 (1912), Nos. 3, pp. 56-63; 4, pp. 73-80, figs. 3; 5, pp. 103-110; 6, pp. 131-139; 7, pp. 151-158).—Continuing previous work (*E. S. R.*, 23, p. 212), the author now points out that the digestion of casein is not the only factor upon which the typical structure of Edam and other cheeses depends. This work was conducted for the purpose of studying the following points: (1) The fixation of lactic acid by casein; (2) the relation which the structure of the cheese has to the acidity and the sodium chlorid concentration; and (3) the neutralizing capacity of the bodies which are precipitated from milk by rennet.

By physico-chemical methods it was determined that lactic acid was capable of fixing a certain amount of casein (4.25 per cent of its weight). The casein lactate thus formed was very easily hydrolyzed by water. The fixing of this amount of lactic acid, according to the author, gives a full explanation for the small amounts of lactic acid found in Edam cheeses in the work previously reported. No reason, therefore, exists for differentiating between calcium

monolactate and bilactate, and the results obtained point to the view that a calcium phosphocaseinate exists in milk in solution. It was further noted that the greater or lesser swelling of the cheese mass, upon mixing with lactic acid and 5 per cent of sodium chlorid, is a function of the hydrogen ion concentration. This fault in cheese making may, therefore, be said to be due to insufficient swelling of the calcium lactocaseinate under the influence of the sodium chlorid and hydrogen ions.

Tests were also conducted to determine the influence of the concentration of the sodium chlorid of the cheese moisture upon the swelling of the cheese mass. The maximal swelling was found to set in at the concentration of  $\pm 5$  per cent, which is found in practice to be the normal. At a lower or higher concentration the rate of swelling decreases. The curves obtained in this work also explain the formation of the so-called salty crust of Edam cheese. In a concentration of from 10 to 15 per cent of sodium chlorid in the cheese moisture no swelling of the casein takes place. This phenomenon is a colloidal-chemical and not a bacteriological one. The formation of heavy crusts in cheeses can also be explained in the light of colloid chemistry (Gels). In caseifying certain milks it was noted that the acidity of the cheese mass as noted had no relation to the neutralizing properties of the substances precipitated by rennet. The production of short cheeses from calcium-poor milks has no relation to the lesser neutralizing property of such milks, but they are a factor in so far that they have a tendency to retain too much whey, and this results in the production of a sour cheese. Milk sugar is also a factor in this case.

Some tests are also included which deal with the factors which influence the moisture content of the cheese mass. These will be reported upon at a later date. The results of some experiments are given which tend to set aside the conception that the peptonization of casein is not due to bacterial action.

On the consistency of the cheese mass, F. W. J. BOEKHOUT and J. J. OTT DE VRIES (*Centbl. Bakt. [etc.], 2. Abt., 33 (1912), No. 25, pp. 609-617, fig. 1*).—A critical discussion of the article noted above.

Brinsen cheese, WINKLER (*Österr. Milk. Ztg., 19 (1912), No. 16, pp. 241-243, figs. 5*).—The different methods of making Brinsen cheese are described.

White Gorgonzola cheese, trans. by J. H. MONRAD (*N. Y. Produce Rev. and Amer. Cream., 34 (1912), No. 18, p. 793*).—The contrasts between the methods of making white and green Gorgonzola cheese are pointed out.

## VETERINARY MEDICINE.

Special pathology and therapeutics of the diseases of domestic animals, F. HUTYRA and J. MAREK, edited by J. R. MOHLER and A. EICHHORN (*Chicago, 1912, vol. 1, pp. XVI+1133, pls. 10, figs. 198*).—An authorized American edition translated from the third revised and enlarged German edition (E. S. R., 26, p. 82).

A manual of veterinary physiology, F. SMITH (*London, 1912, 4. ed., pp. XII+808, pl. 1, figs. 260*).—A fourth revised and enlarged edition of this work.

Compendium of practical toxicology, R. KOBERT (*Kompendium der Praktischen Toxikologie. Stuttgart, 1912, 5. ed., rev. and enl., pp. XII+328*).—This is the fifth edition of this well-known work which has been entirely rewritten and enlarged. It is meant for physicians, health officers, and students.

In regard to the theory of disinfection, R. BETZEL (*Zur Theorie der Desinfektion. Diss. Tech. Hochsch. Karlsruhe, 1911, pp. 64*).—The adsorption of chloroform, silver nitrate, corrosive sublimate, formaldehyde, and phenol at various concentrations by yeast was studied. It was noted that the process of taking up the disinfectant was an adsorption phenomenon. The disinfecting

property of phenol is no simple function of the amount of disinfecting agent taken up by the yeast.

**Antitoxin and protein.** P. H. RÖMER (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 13 (1912), No. 3, pp. 260-282*).—The milk from sheep which were previously injected with tetanus antitoxic serum from the horse contained antitoxin. Horse serum protein could not be detected with certainty with the aid of the complement fixation and precipitation methods. The serum of sheep which were treated by various methods with tetanus antitoxin obtained from the horse showed the presence of this antitoxin for a period of six months thereafter, while the substances which can be precipitated by antiserum vanished long before this period.

**About neosalvarsan.** E. SCHREIBER (*München. Med. Wchnschr., 59 (1912), No. 17, pp. 905-907; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 54 (1912), No. 3, pp. 82, 83*).—Neosalvarsan is a monobody which results from the condensation of sodium formaldehyde-sulphoxylate with salvarsan. It is easily and neutrally soluble in water. According to Ehrlich it is more toxic to the trypanosomes than salvarsan, about 1 gm. being as toxic as 1.5 gm. of salvarsan. The main thesis of this work was in regard to spirochete infections (lues) in man.

**The action of salvarsan on anthrax.** SCHUSTER (*Abs. in Ann. Méd. Vét., 61 (1912), No. 6, p. 342*).—Experiments show that salvarsan exerts a specific action on the anthrax bacillus. When an injection of salvarsan was made simultaneously with the inoculation of a virulent culture of the anthrax bacillus no signs of the disease appeared. Recovery resulted when the injection of salvarsan was made from 1 to 12 hours after the rabbit was experimentally infected.

**Contribution to our knowledge of the precipitin reaction as an aid for diagnosing anthrax.** PROFÉ (*Centbl. Bakt. [etc.], 1. Abt., Orig., 64 (1912), Festschrift F. Loefler, pp. 185-189*).—The author sought to determine in what way the method and time of heating the anthrax material influenced the results obtained with the precipitin reaction. Repeated boiling of the material from animals suffering from anthrax in an aqueous or saline solution over the direct flame has no more effect upon the precipitinogen than keeping it in boiling water from 5 to 45 minutes.

The chloroform precipitation method (E. S. R., 27, p. 80) has the advantage over the heating method in that it yields clearer extracts and gives a sharper reaction. A modification of the chloroform method is given.

**Report of the departmental committee appointed by the president of the Board of Agriculture and Fisheries to inquire into foot-and-mouth disease** (*Rpt. Dept. Com. Bd. Agr. and Fisheries [Gt. Britain], Foot-and-Mouth Disease, 1912, pts. 1, pp. 12; 2, pp. III+337*).—This is the report of a committee of 12 appointed November 17, 1911, to inquire into the recent outbreaks of foot-and-mouth disease in England and to consider measures to prevent their recurrence. The committee also extended its inquiry to anthrax, since any measures as to imports which would be preventive of anthrax would also be effective against foot-and-mouth disease. The report takes up the history of foot-and-mouth disease in Great Britain, gives a description of it, and discusses experiments and research into foot-and-mouth and other diseases, preventive inoculation and experimentation with virus of a dangerous nature in Great Britain, origin of outbreaks, means by which the virus may be imported, etc.

The committee are of the opinion that all persons employed as knackers or slaughterers, as well as all owners of stock, should be required to report immediately any observed case of the disease. If hides and skins from infected countries are sterilized prior to shipment there will be no necessity for

cleansing and disinfecting holds of ships, trucks, and freight cars in or on which they have been carried. The sweepings of holds of ships are considered a source of danger, and it is recommended that they be destroyed or thrown overboard and not allowed to land.

The second part of this report consists of minutes of evidence and appendixes in which are presented details of outbreaks of foot-and-mouth disease in each county of Great Britain, 1870 to 1911, a translation of a paper by B. Bang on foot-and-mouth disease, and a summary of passenger traffic to the United Kingdom from Europe. An index to the evidence of the 32 witnesses is also given.

The diagnosis of glanders by the complement fixation and the agglutination test, NEVERMANN (*Berlin. Tierärztl. Wchenschr.*, 27 (1911), No. 52, pp. 954, 955).—No case of glanders occurred after all animals detected with the blood tests had been removed. On the basis of blood tests 160 horses were destroyed, of which 134, or 83.7 per cent, were found to be glanderous.

The utilization of anaphylaxis for diagnosing glanders, H. MIESSNER (*Centbl. Bakt. [etc.]*, 1. Abt., *Orig.*, 56 (1910), No. 5-6, pp. 537-542; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., *Ref.*, 49 (1911), No. 6, p. 177).—This test is considered of no value for diagnosing glanders.

Melitensis and paramelitensis, L. NÈGRE and M. RAYNAUD (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 18, pp. 791-793; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II. *Ref.*, 5 (1912), No. 13, pp. 296, 297).—A coccus is described which culturally and morphologically strictly resembles the *Micrococcus melitensis*, but is distinguished from it by not agglutinating with a specific Malta fever serum. The serum obtained with this organism, on the other hand, will not agglutinate the *M. melitensis*.

Contribution to the diagnosis of tuberculosis (with the sputum) with the aid of the protein test, B. NICOLA (*Riv. Ig. e Sanit. Pub.*, 22 (1911), No. 8, pp. 233-237; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II. *Ref.*, 5 (1912), No. 2, pp. 923, 924).—This is an investigation of the value of Roger's protein reaction.

The conclusion reached is that the test is a good one for detecting acute and chronic tuberculosis as long as the secretion is obtained from the lungs. A bronchial secretion will not give the test. Positive reactions may at times be obtained in lobular pneumonia, bronchial pneumonia, and in congestions which result from heart and kidney insufficiencies.

Action of certain glycerol esters upon the tubercle bacillus, A. T. SALIMBENI (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 5, pp. 368-370).—In most of the tests the author utilized mono-, di-, and trichlorhydrin esters of glycerol.

In the preliminary tests it was found that mono- and dichlorhydrin dissolved the fatty material extracted with acetone from the tubercle bacillus in the cold; also a waxy substance extracted from the tubercle bacillus by chloroform, but insoluble in acetone. Trichlorhydrin ester dissolves these waxes and fats very rapidly.

As a result the author made a study of the behavior of the tubercle bacillus when treated with these esters. The trichlorhydrin ester destroyed the acid resisting powers of the tubercle bacillus and the organisms became granular and easily took the blue stains. The ester acted more strongly on the organism than either mono- or dichlorhydrin esters. A large quantity of the mass insoluble in the esters was soluble in water.

The action of certain products obtained from the tubercle bacillus, B. WHITE and O. T. AVERY (*Jour. Med. Research*, 26 (1912), No. 2, pp. 317-356).—“Tuberculo-protein treated by the method of Vaughan yields a poisonous substance (called toxophore by Vaughan), which, in suitable doses, produces in

normal guinea pigs an intoxication resembling, if not identical with, the specific immediate protein intoxication in hypersensitive pigs. The gross pathological findings appear to be similar in both conditions. The minimum fatal dose of 2 preparations was 1 part to 15,000 parts of body weight. Boiling for 1 minute with filtration does not affect the potency of the watery solution.

"Fatal doses of the poison cause an abrupt fall in temperature. Smaller amounts (up to 0.01 gm. for pigs from 200 to 250 gm.) are apparently without appreciable effect on the body temperature. Under the experimental conditions noted, repeated increasing doses of poison fail to render animals immune to a minimum fatal dose. Survival from a large intravenous dose of the poison apparently renders the animal refractory, for 48 hours at least, to an amount in excess of that required to kill. Fresh brain, lung, and liver tissue, under the conditions noted, showed no binding or neutralizing affinity for the poison. Normal guinea pig serum has little if any destructive action on the cell poison. Intradermic injections of 0.00005 gm. of the poison produced no local reactions in normal or sensitized pigs.

"Atropin sulphate protected 75 per cent of the animals from a synchronous injection of fatal amounts of poison. Morphine sulphate aborts the acute symptoms and delays death, and in 2 cases completely protected from fatal intoxication. Chloral hydrate protected many of the animals against an otherwise fatal dose of the poison, and inhibited the acute manifestations and delayed death in others. Lecithin emulsion injected simultaneously with the poison seems to possess a slight and irregular prophylactic action. Incubation of the poison with lecithin emulsion for 1 hour at 27.5° C. increases this neutralizing property. A dose of 1:12,000 of the poison was not affected. The preliminary administration of lecithin protected some of the animals, delayed death in others, and was without effect in the remainder. The results were too inconstant to warrant definite conclusions."

A bibliography embracing 17 titles is included.

**Protective vaccination against tuberculosis with killed tubercle bacilli contained in reed sacks,** G. HEYMANS (*Deut. Med. Wchnschr.*, 38 (1912), No. 23, pp. 1081, 1082; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 5 (1912), No. 13, p. 317).—Living tubercle bacilli when contained in these sacks migrate through the capillaries of the vegetable vascular tissues (bacterial ultradiapedesis). By treating the reed sacks with collodion this migration can be stimulated or inhibited.

Tubercle bacilli killed with alcohol are well borne up to 1 gm. of substance by sound or tubercular animals. In some instances immunizing properties (protective and curative) were noted.

**The treatment of tuberculosis with paratoxin,** G. LEMOINE (*Rev. Mod. Méd. et Chirurg.*, 10 (1912), No. 1, pp. 6-11; *abs. in Internat. Centbl. Gesam. Tuberkulose Forsch.*, 6 (1912), No. 7, pp. 365, 366).—Paratoxin is an extract of the gall and contains lipid-like substances which possess an antibacillary power. They probably exert their power in conjunction with the phagocytes. Several thousand patients treated with this preparation showed a decrease in bacterial toxemia, which was probably due to a diminution of the number of bacteria in the body.

**Tuberculosis in cattle** (*Brit. Med. Jour.*, 1912, No. 2692, pp. 263, 264).—A statistical and general discussion by Delépine and Wilson in regard to the occurrence of tuberculosis in Germany, France, Great Britain, and Denmark at a conference of the veterinary association held at Melbourne.

**The agglutination test in the diagnosis of bovine contagious abortion,** J. McFADYEN and S. STOCKMAN (*Jour. Compar. Path. and Ther.*, 25 (1912),

*No. 1, pp. 22-38*).—Continuing work previously noted (*E. S. R.*, 22, p. 584), the authors now report results of further tests with nearly 700 animals. In their opinion the test has now passed the probationary stage and deserves to be adopted as a method for diagnosing suspected cases of contagious abortion.

**Tuberculosis in the goat**, M. G. MOREL (*Hyg. Viande et Lait*, 5 (1911), *No. 11, pp. 642-646*).—This article points out the dangers which surround the utilization of raw milk obtained from tuberculous goats.

**Experiments to determine the safe dose of white arsenic, Cooper's dip, and bluestone for sheep**, A. THEILER (*Agr. Jour. Union So. Africa*, 3 (1912), *No. 3, pp. 321-351, figs. 2*).—The author has conducted a large series of experiments on sheep with a view to determining the maximal reliable dose of these drugs and mixtures thereof, which are frequently used in South Africa for the treatment of many diseases of all classes of domesticated stock, but more particularly in the treatment of sheep affected both with wireworms and tapeworms.

"It appears that arsenious oxid in the dose of 15, 30, and 45 grains is a safe dose for sheep, but it would not be wise to use the largest dose on a great number of sheep. . . . Cooper's dip administered to sheep in the doses of 15 grains had no fatal effect on 30 sheep. The 15 sheep belonging to the lot of 'watered 24 hours previous to and after dosing' were noticed to be 'off feed' the day following. With the dose of 30 grains, 48 sheep were dosed and 1 died the day following. . . . The dose of 22 grains bluestone appears to represent a safe dose for sheep; it may probably be slightly increased. The dose of 45 grains and more may cause death. . . . The dose of 30 grains white arsenic, mixed with 30 grains of bluestone, does not appear to be a safe dose for sheep. . . . The dose of 15 grains of Cooper's dip, added to 15 grains of bluestone, given in a mixture, seems to be a safe dose for a sheep. . . . A safe dose of a mixture of Cooper's dip and bluestone, when mixed with 2 substances which are considered to be harmless, such as salt and sulphur, became toxic, and caused death amongst the treated sheep."

The details of the post-mortem lesions in the 2 sheep which died from poisoning by arsenious oxid are presented in an appendix.

**The importance of hog cholera and the production of hog-cholera serum**, F. A. BOLSER (*Amer. Vet. Rev.*, 40 (1912), *Nos. 5, pp. 611-618; 6, pp. 765-771*).—This is a discussion of the history, geographical distribution, pathology, symptoms, and methods of treatment. It also discusses the preparation of the Dorset-Niles serum against hog cholera and describes its use.

**Hog cholera** (*Ann. Rpt. Bd. Livc Stock Comrs. Ill.*, 25 (1910), *pp. 66-70, pls. 4*).—This is a discussion of the nature of hog cholera, its distribution in Illinois, and the methods of preparing and using prophylactic hog-cholera serum.

**Protective vaccination against hog cholera**, J. GYÁRFÁS (*Állatorvosi Lapok*, 35 (1912), *No. 25, p. 291-293; abs. in Berlin Tierärztl. Wchnschr.*, 28 (1912), *No. 31, p. 569*).—Vaccinations were made with the Hutyra hog-cholera serum and 1,592 hogs. Previous to the vaccination 14 hogs died and the epizootic was considerably advanced. After vaccination 353 animals died. In another locality out of 478 pigs vaccinated 2 died, and in a third barn where the vaccinations involved 507 head the loss was 9.4 per cent. The serum has no curative action according to the author.

**Some investigations in regard to hog erysipelas, immune serum, and its action in the animal body**, H. HOLTH (*Maanedskr. Dyrlæger*, 24 (1912), *No. 6, pp. 145-179; abs. in Berlin Tierärztl. Wchnschr.*, 28 (1912), *No. 31, pp. 568, 569*).—Hog erysipelas immune serum does not possess any bactericidal properties, but contains relatively large amounts of specific agglutinins and ambo-

ceptors. Its activity depends upon the presence of antiaggressins which are antagonistic to the cellular toxins produced in the organism (body). Erysipelas serum stimulates phagocytosis only indirectly. -

**Tuberculosis of hogs, J. R. MOHLER and H. J. WASHBURN** (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 201, pp. 40, figs. 5*).—This is a revision of Circular 144 previously noted (*E. S. R.*, 20, p. 982).

**Autotherapy—its application in the treatment of septic diseases in the horse, D. J. MANGAN** (*Amer. Vet. Rev.*, 41 (1912), No. 4, pp. 422-433).—Autotherapy, as proposed by Duncan, consists chiefly of the administration of crude autogenous pus. This method was tried with 12 horses, chiefly pyogenic infections, and possesses the advantage of not necessitating the preparation of a vaccine in a culture medium which is foreign to the organism. The results obtained were in most instances good.

**Chronic catarrh in the uterus in a mare, V. S. PSCHORR** (*München. Tierärztl. Wchuschr.*, 55 (1911), No. 5, p. 70; *abs. in Vet. Rec.*, 23 (1911), No. 1192, p. 720).—A case diagnosed as uterine catarrh was found in a mare which would not breed and from the uterus of which a liter of whitish yellow stringy discharge was obtained. Aspiration with a catheter removed a bulk of 4 liters of fluid.

For treating the condition 5 liters of a solution of creolin was injected (dilution not given) and drained out. Then  $\frac{1}{2}$  liter of a 2 per cent protargol solution was given in the same manner, but left in the uterus. After the fourth day no discharge was present, and none has been seen since.

**What is the deadly new horse disease? (Twentieth Cent. Farmer, 1912, No. 615, pp. 6, 7, figs. 5)**.—A discussion of the outbreak of so-called cerebrospinal meningitis, which during the third week in August became epidemic in central and western Kansas and during the last week in the month crossed into Nebraska.

**It's a pasture disease that is killing the horses (Farmers Mail and Breeze, 42 (1912), No. 27, pp. 3, 16, 17, figs. 2)**.—This paper discusses the occurrence of the disease of horses in Kansas and Nebraska noted above.

**Intracellular bodies associated with equine anemia, W. B. MACK** (*Proc. Amer. Vet. Med. Assoc.*, 48 (1911), pp. 378-382, pl. 1).—In a bulletin on equine anemia, previously noted (*E. S. R.*, 21, p. 584), the author referred to certain spherical bodies observed in the red blood corpuscles of individuals suffering from the disease. A further study has shown them to be present in every case of equine anemia studied and that they stain well by certain methods.

"In blood films properly fixed and stained they appear within the red corpuscles as small 'coccus-like' bodies or points, stained an intense, deep blue. They vary in size from about  $1 \mu$  in diameter to the smallest visible points. The form most frequently encountered is from about  $\frac{1}{2}$  to  $1 \mu$  in size, spherical in form, with outlines definite and clean cut. Slightly elongated forms occasionally occur. As a rule a corpuscle contains but 1, rarely 2 are found in the same cell. In some instances where 2 are included in a corpuscle they lie close together, apparently in contact, others are separated by about one-half the diameter of one of them, others again are more widely separated. In a majority of such instances the bodies or granules are about equal in size, but sometimes one of them is slightly larger than the other. Some of these bodies lie near the center of the corpuscle, others toward or at the periphery. Occasionally one appears to protrude from the cell containing it. Bodies identical in size, form, and staining reaction are frequently found outside the corpuscles, i. e., free in the fluid portion of the blood.

"Of the smaller forms frequently 2 or 3, rarely as many as 5 or 6, are found within a corpuscle, usually some distance apart. In such instances they may

be equal in size or one may be distinctly larger than the others. Frequently the space between them is stained less intensely than the remainder of the corpuscle and this somewhat clearer space bounded by faint, thread-like lines with just a suspicion of blue stain in them.

"Occasionally ring-shaped bodies, faintly defined, with a slightly bluish tint, are observed with usually 1, rarely 2 or 3, deeply stained granules situated at the periphery of the ring. They are very minute and easily overlooked. Whether the smaller forms bear any relation to the larger, 'coccus-like' bodies first mentioned remains to be determined. These bodies may be seen in slides fixed in methyl alcohol and unstained. . . .

"The frequency with which these bodies occur varies widely in different cases. In some they are comparatively few in numbers, in others numerous. . . . A diligent search for them in blood films prepared from several supposedly normal horses, several affected with pneumonia, influenza, strangles, etc., and from several surgical cases has failed to reveal them."

The "coccus-like" form is said to quite closely resemble the description and photographs of the protozoan genus *Anaplasma* described by Theiler as the cause of gall sickness in South African cattle. It is suggested that these bodies may be found to represent a new species of *Anaplasma*.

In sections of the liver from a typical case of equine anemia, stained by the Gram-Weigert method, the author found inside the hepatic cells certain very minute, ring-shaped bodies with a small granule at one side, at the periphery of the ring. Search for them in sections of liver from several animals where the liver showed various types and degrees of degeneration resulted negatively. The author thinks these ring-shaped bodies to be too definite and too uniform for degeneration products, as supposed by Todd and Wolbach (*E. S. R.*, 25, p. 89) in work with swamp fever.

Studies on the etiology of equine influenza, N. S. FERRY (*Vet. Jour.*, 68 (1912), No. 442, pp. 185-197).—The data presented in this paper, which was read at the meeting of the Society of American Bacteriologists at Washington, D. C., in December, 1911, have been noted from another source (*E. S. R.*, 27, p. 86).

The etiology of equine influenza (*Vet. Jour.*, 68 (1912), No. 443, pp. 246-248).—This is a review of the paper noted above.

Glanders of the lungs in horses with some notes on the serological detection of the disease, SCHÜTZ (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 64 (1912), *Festschrift F. Loeffler*, pp. 87-99).—The glanderous nodules in the lungs of horses are either hematogenic or bronchogenic in origin. The following varieties of pulmonary infections with the glanders bacillus are mentioned and discussed in detail: (1) A glanderous cellular or cellular fibrinous inflammation of the lungs; (2) chronic (glanderous) indurative pneumonia and broncho-pneumonia; and (3) purulent bronchitis and peribronchitis. Mixed infections are also described. The agglutination and complement fixation tests are good methods for detecting this disease in horses.

A contribution on the treatment of contagious pneumonia of the horse with salvarsan, JACOB (*Ztschr. Veterinärk.*, 23 (1911), No. 8-9, pp. 406-411; *abs. in Berlin. Tierärztl. Wchnschr.*, 28 (1912), No. 32, p. 588).—In all of 12 cases of the pectoral form of influenza (brustseuche) in which the author administered salvarsan intravenously the temperature sank to normal within from 15 to 24 hours and continued so.

Bovine variola in chickens, O. CASAGRANDE (*Rev. Internat. Vaccine*, 1 (1910), No. 1, pp. 1-27, pls. 3; *abs. in Bul. Inst. Pasteur*, 9 (1911), No. 21, pp. 939, 940).—By inoculating the vaccine upon the skin or epithelium of chickens, which has been scarified or rubbed with sandpaper, the specific lesions (Cy-

toryctes) were produced. Young chickens were more susceptible to the vaccines than older birds. The skin of the thorax was particularly susceptible, more so than that of the wattles. The cornea was less sensitive. By inoculating the skin of the thorax many times successively immunity could not be produced, but inoculating a part of the wattle immunized the barb entirely. The author believes that chickens can be used for controlling vaccine virus.

An investigation of an outbreak of septicemia in poultry, R. A. WHITING (*Amer. Vet. Rev.*, 41 (1912), No. 4, pp. 456-459).—A mortality of about 90 per cent in a flock consisting of 70 chickens and 12 turkeys was caused by an organism of the hemorrhagic septicemia group.

In regard to the growth and virulence of the organisms causing tuberculosis in fowls, C. WALTHER (*Arch. Path. Anat. u. Physiol. [Virchow]*, 207 (1912), No. 1, pp. 140-148; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 5 (1912), No. 3, p. 19).—There are strains of the avian tubercle bacilli which culturally resemble the human type of bacilli, and which on inoculation (crude material or fresh cultures) show a high virulence for guinea pigs. After cultivating these organisms for a longer time than usual on artificial media the strains become more like the regulation avian tubercle bacilli. No appreciable reduction in virulence, as noted by other workers, could be determined.

## RURAL ENGINEERING.

Irrigation: Its principles and practice as a branch of engineering, H. BROWN (*London, 1912, 2. cd., rev., pp. XV+301, pls. 9, figs. 68*).—This work deals with the practice of irrigation as a branch of engineering, sets forth the fundamental principles that should govern such practice and furnishes illustrations of their application to existing canal systems. It contains chapters on irrigation and its effects; basin irrigation; perennial irrigation and water duty; sources of supply; dams and reservoirs; methods of construction; means of distribution; masonry works; methods of distribution, assessment of rates, and administration; river training; agricultural operations and reclamation works; and navigation.

Some methods of measuring irrigation water practiced by the United States Reclamation Service (*Engin. and Contract.*, 38 (1912), No. 8, pp. 215-217, figs. 13).—This is an abstract of a paper read by W. G. Steward before the Idaho Engineering Society, in which he describes canal, weir, and automatic gages, and gives discharge tables and discharge curves for different weirs and orifices used in water measurement under varying circumstances.

Irrigation: California. R. P. TEELE (*Washington: Bur. Census [U. S.]*, 1910, pp. 14, figs. 2).—This article contains irrigation statistics for California dealing with the farms, acreage, and crops irrigated, irrigation works, and the cost of construction, operation, and maintenance.

Twenty-second annual report of the hydraulic engineer, J. B. HENDERSON (*Ann. Rpt. Hydraul. Engin. Queensland*, 22 (1911), pp. 22+68, pls. 36).—This reports the results of irrigation, power, and underground water investigations and surveys, and gives rainfall and hydrographic data and maps.

Experiments on the use of water for irrigation in South Africa, J. MULLIE (*Bul. Agr. Congo Belge*, 3 (1912), No. 2, pp. 481-497, figs. 2).—A discussion of the methods of irrigation employed, the duty of water, the drainage of irrigated soils, and the amount and frequency of irrigation required to satisfy the crops and soil conditions in South Africa.

Construction difficulties in the draining of irrigated lands, R. A. HART (*Nat. Land and Irrig. Jour.*, 6 (1912), No. 2, pp. 23-27, figs. 6).—It is stated

that the nature of the soil itself is one of the chief factors tending to make the construction of drains in irrigated lands extremely difficult, and that where open ditch drains are required great difficulty is experienced in constructing them so that they will hold their shape. Because of this, covered tile drains are much more desirable in irrigated lands than open drains. The methods of design and construction of tile and open drains, intended to overcome as nearly as possible the difficulties presented by the soil conditions, are outlined.

[Methods of the preliminary organization of a 450,000-acre drainage and levee project in southeastern Missouri], L. T. BERTHE (*Engin. and Contract.*, 38 (1912), No. 5, pp. 131-133, fig. 1).—This article outlines the conditions and methods of bringing about the organization of this project, including a description of the district and its organization. The preliminary cost estimate was \$2,585,000.

The scoop wheel as the pioneer for the drainage of lowlands, J. D. BECK (*La. Planter*, 49 (1912), No. 9, pp. 141, 142, fig. 1).—A discussion of the design, construction, and operation of the scoop wheel as used in drainage reclamation, outlining in detail the design of a 27 ft. wheel which has a possible actual discharge of 7,153 cu. ft. per minute at low lift. Several installations in operation in different localities are described, giving efficiencies ranging from 33 to 89 per cent.

Drainage by explosives, A. MACPIERSON (*Jour. New Zeal. Dept. Agr.*, 5 (1912), No. 2, pp. 126-133, figs. 3).—This reports the results of experiments on the dynamiting of pakihī soil for drainage in Westland, New Zealand.

The soil was from 11 to 21 in. deep, above 2 or 3 alternate layers of hard packed sand and boulders on cement formation and iron pan from 9 to 22 in. in thickness, with a porous substratum of free sand, shingles, and boulders several feet in depth. The charge holes were bored 4 ft. apart, into and through the hard bottom. The first 2 plats were charged with 2 sticks of dynamite per hole, the third and fourth plats with 3 and 4 sticks, and the fifth and sixth plats with 5 sticks per hole.

The iron pan was not fractured by the explosion in any of the plats, holes about 1 ft. in diameter being the extent of its operation, yet the drainage through these holes has so far been fairly successful.

Roads, paths, and bridges, L. W. PAGE (*New York*, 1912, pp. XIV+263, pls. 24, figs. 12).—This book gives in concise and elementary form the fundamental principles governing the construction of roads, paths, and bridges for farm and neighborhood purposes, and outlines in detail the selection of material and methods of construction and maintenance. It contains chapters on the history of road building; road legislation and administration; locations, surveys, plans, and specifications; earth, sand-clay, gravel, and broken stone roads; selection of materials for macadam roads; maintenance and repair; roadside treatment; modern road problems; paths; and culverts and bridges.

Handbook for highway engineers, W. G. HARGER and E. A. BONNEY (*New York and London*, 1912, pp. XIV+493, figs. 85).—This book contains in compact form information ordinarily required in the field and office practice of road design and construction. It contains data for the inexperienced engineer or commissioner on the relative importance of the different parts of the design and the possibilities of economy without impairing the efficiency of the roads, and also cost data useful to anyone engaged in road work.

A third report on the public roads in Georgia, S. W. MCCALLIE (*Geol. Survey Ga. Bul.* 28, 1912, pp. 12).—A report of the mileage of and expenditures on public roads in Georgia, given by counties for the year 1911, and calling attention to the increase in road mileage and to the profitable use of convict

labor. The total mileage is given as 83,586 miles; and the total expenditure on roads and bridges during 1911 as \$4,127,899.

**Practice of the Massachusetts Highway Commission in the construction and maintenance of state highways** (*Engin. and Contract.*, 38 (1912), No. 8, pp. 298, 299).—This is an abstract of a paper read by A. W. Dean before the Boston Society of Civil Engineers in which he describes the methods of construction and maintenance of the state highways of Massachusetts, more especially of bituminous and bituminous macadam roads.

**An investigation of the road making properties of Missouri stone and gravel.** W. S. WILLIAMS and R. W. ROBERTS (*Univ. Mo. Engin. Expt. Sta. Bul.*, 2 (1911), No. 3, pp. 70, figs. 10).—Descriptions of the abrasion, cementation, impact, hardness, toughness, and absorption tests as applied to Missouri stone and gravel are followed by the results of investigations in each county and tabulated data giving the results of tests on the materials.

Limestone is the most abundant road material in the State, but only about 38 per cent of it will stand all the tests. It has good cementing qualities, however, and can be used as a base for macadam. The best road materials found are the granites, rhyolite, and porphyry, which have good cementing qualities and may be used for wearing surfaces. The gravel in the State is chiefly chert and flint and is classed as poor road material.

**The road building materials of Coshocton County, Ohio.** F. H. EXO (*Ohio State Univ. Bul.*, 16 (1912), No. 37, pp. 29, pls. 10, fig. 1).—This bulletin discusses the road materials of this county, presents simple effective methods for using them for road improvement at a reasonable first cost, and gives the results of standard tests on these materials of which the largest part is limestone, gravel, and sandstone. The conclusions are that although this county does not have an abundance of permanent road material, by carefully selecting the best available material and following approved methods of construction under the direction of a competent engineer, good roads may be secured at reasonable first cost and farm values may be increased.

**Methods of testing road making materials in European countries** (*Engin. and Contract.*, 38 (1912), No. 11, pp. 293-298, fig. 1).—This is an abstract of a report by A. Mesnager to the International Association for Testing Materials, containing a list of the road building materials used and an outline of the methods employed in testing them in Germany, Austria, Belgium, Denmark, Budapest, Norway, and the Netherlands.

**Road maintenance problems.** J. G. POWELL (*Surveyor*, 42 (1912), No. 1075, pp. 271, 272).—An extract from the annual report of the county engineer of Wiltshire, England, stating that the chief difficulties encountered in road maintenance are the heavy traffic and consequent wear and tear on the roads during periods of alternate frost and thaw, the existence of soft, yielding subsoil for road beds, the high growth of hedges and trees, and the wear produced by the increased number of mechanically propelled vehicles. It is further stated that roads to bear motor vehicle traffic must have new unyielding sub-bases as well as resurfacing, and that flint for surfacing is cheaper and more satisfactory than limestone in this locality.

**Reinforced concrete design.** O. FABER and P. G. BOWIE (*London*, 1912, pp. XIX+332, figs. 160).—This book presents the fundamental principles underlying the practical design of reinforced concrete, which are to be used in connection with practical work and in experiments in determining the proper design to suit any local conditions. It deals with several important new considerations among which are the ratio of live to dead load as affecting the bending moment of beams, and the relative stiffness of beams and columns.

**Dynamite on the farm** (*Agr. Jour. Union So. Africa*, 3 (1912), No. 6, pp. 892-896).—This article notes the results obtained by subsoiling with gelignite, a high velocity explosive, and with specially prepared agricultural dynamite, a low velocity explosive. In using the gelignite the charges were sunk from  $3\frac{1}{2}$  to  $5\frac{1}{2}$  ft., the best results being obtained from the shallower charges. The dynamite gave much better results than gelignite, since, as a low velocity explosive, it pulverized the subsoil over a much larger area. The facts as noted indicate that for success and safety the work must be carefully and properly handled. "Rules of thumb" must be avoided and nothing but the correct implements and explosive to satisfy local conditions must be used.

**Study of agricultural machinery**, M. ESTRADA (*Bol. Min. Agr. [Buenos Aires]*, 17 (1912), No. 4, pp. 337-344).—A discussion of experimental work on agricultural machinery in Argentina and the United States and of agricultural engineering education in the United States, dealing especially with motor machinery, rural architecture, sanitation, irrigation, and drainage.

**How the plow hitch affects draft** (*Threshermen's Rev.*, 21 (1912), No. 3, pp. 9, 44, 46, 48, figs. 3).—A graphical and mathematical analysis of draft and a few suggestions pertaining to the hitching of engine gang plows are given.

The conclusions are drawn that the best results are obtained by making the hitch a little to the right of the center of the plow and by hitching as high on the engine as possible without carrying the front end of the plow off the ground, and that the larger the plow the more economical it is in power. From the graphical analysis the formula is deduced for the desired hitch for any sized plow of  $D = \frac{AC}{2C+B}$ , in which  $D$  = the distance in inches from the first plow center to the hitch,  $A$  = distance from the center of the first plow to the center of the last plow, measured at right angles to the furrow,  $B$  = the distance from the center of the first plow to the center of the last plow, measured parallel to the furrow, and  $C$  = the distance in inches from the front plow bottom to the engine draw bar. For practical conditions 12 in. should be added to  $D$ .

**Fifth Winnipeg motor contest**, P. S. ROSE (*Amer. Thresherman*, 15 (1912), No. 5, pp. 3-11, figs. 18).—This contest was primarily one of fuel economy, being divided into 3 main divisions: (1) a 2-hour economy brake test during which the engines were supposed to run under their most economical load and have determinations made of the fuel required per horsepower hour; (2) a  $\frac{1}{2}$ -hour maximum brake trial under maximum load, with a fuel and water consumption determination; and (3) a plowing test in which each tractor was given a certain amount of land to plow and accurate records were kept of fuel consumption.

The tractive efficiencies as determined were very high, due to the good ground condition, the gas tractors giving efficiencies from 59 to 83 per cent. The steam engines showed considerably lower efficiencies. The results and accompanying data indicate a 25 per cent increase in average economy since 1910, due principally to advancement in the art of engine building, which is sufficient also to counteract the advance in price of gasoline.

**The status of the motor plow question in Germany**, MARTINY (*Kühn Arch.*, 2 (1912), pt. 1, pp. 193-229, figs. 12).—A general discussion of the theory of operation of the motor plow, presenting graphical and mathematical explanations of the losses by sinking and slipping of drive wheels in different types, the action of plowshares in different hitches, etc., followed by the results of practical experiments and by discussions of the efficiency, practicability, and flexibility of various types.

**Tests of motor plows.** B. MARTINY (*Mitt. Prüf. Stat. Landw. Masch. u. Geräte, Halle, 1912, No. 163, pp. 46, fig. 1*).—The methods and results of tests are given of 3 types of motor ground breaker, namely, the ordinary motor plow, the motor plane plow, and the combination motor and rotary ground breaker. A general discussion is given of the methods of motor operation and draft employed by different makes, the power required, and the results obtained under varying conditions of soil and weather.

**Agricultural motor trials in Algeria** (*Impl. and Mach. Rev., 38 (1912), No. 449, pp. 651-653, figs. 5*).—This article compares the results of several sets of plowing trials on motor tractors taken at different times of the year under varying conditions of soil and atmosphere. The results show the fallacy of judging the machines and overestimating the results as obtained from the tests of only 2 or 3 days' duration, as has been the custom, and indicate that a comparison is only possible when the machines are employed for various conditions of work over the greater part of the year.

**Gasoline as a fuel for motor use** (*Farm Machinery, 1912, Nos. 1087, pp. 32, 34; 1088, pp. 30, 32; 1089, p. 16*).—This is a scientific study of the different grades of gasoline, indicating that gravity is no criterion as to the quality, as is commonly accepted, but that the quality of a gasoline is expressed by its initial, intermediate, and maximum boiling points.

The ordinary gasoline has several boiling points, portions of it vaporizing at low temperatures and others at from low to high temperatures. For easy starting, a gasoline engine requires a gasoline with low initial boiling points, but as it warms up it requires higher and higher boiling points in the gasoline to satisfy the increasing demand for power, consequently gasoline to produce the best results in a motor must have low initial boiling points, gradually rising to high boiling points. A high-gravity gasoline is no better than a low-gravity gasoline if they have the same boiling points.

**Steam or electricity in dairy work** (*Molk. Ztg. [Hildesheim], 26 (1912), No. 58, pp. 1087, 1088; Landw. Masch. u. Geräte, 12 (1912), No. 17, pp. [1-7]*).—A comparison of the uses of steam and electricity in an average small dairy, giving the daily and yearly cost figures for the operation of a 10-horsepower steam engine and an 8-horsepower electric motor. It indicates that electric power must cost as low 2½ cts. per kilowatt hour in order to give the economy of steam when both machinery driving and milk and water heating are taken into consideration.

**Library of Agriculture—Country life conveniences and enjoyments**, edited by H. M. SKINNER and A. L. MCCREDIE (*Chicago, 1912, vol. 8, pp. 502, figs. 61*).—This book is made up chiefly of reprints of Farmers' Bulletins of the U. S. Department of Agriculture.

## RURAL ECONOMICS.

[Questions relating to rural economics], H. L. RUSSELL ET AL. (*Bul. Univ. Wis., 1912, No. 509, pp. 125, figs. 24*).—This bulletin presents the papers given at the Second Wisconsin Country Life Conference conducted under the auspices of the College of Agriculture of the University of Wisconsin. Among those relating directly to the economic side of country life the following are noted: Value of Cooperation Among Farmers, by G. F. Comings; Efficient Use of Labor on the Farm, by H. C. Taylor; Hired Labor on the Farm and in the Home, by W. L. Nelson, and The Decline in Rural Population, by B. H. Hibbard.

**Financing the farm**, M. T. HERRICK (*Addresses Ann. Meeting Ohio Bd. Agr., 1912, pp. 28-43*).—An address delivered at the annual meeting of the Ohio State Board of Agriculture, Columbus, Ohio, January 10, 11, 1912, in which the author illustrates the economic significance of scientific methods in farming by statistics

of the production per acre of the leading crops in countries where such methods have been applied and where not applied. He also draws attention to the part played in Germany and France by agricultural cooperative societies in promoting scientific farming by teaching farmers to appreciate the possibilities of scientific methods, and by supplying them with funds to make the needed changes and improvements. He discusses at length the systems of agricultural credit in France and Germany and their possible application to conditions in the United States.

**Agricultural cooperation in Ireland**, C. POE (*Prog. Farmer*, 27 (1912), Nos. 30, pp. 11, 18; 31, pp. 11, 19).—This is a popular article describing in more or less detail the work of cooperative credit banks, cooperative creameries, poultry societies, etc., in Ireland, with suggestions as to the possible application of the principles involved in the South.

**Live stock improvement syndicates in France and recent state encouragement** (*Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intcl.*, 3 (1912), No. 5, pp. 15-31).—This article gives special attention to the active movement of syndicates in live-stock improvement in France, and the recent encouragement from the government and various public bodies.

The chief objects of the syndicates are the purchase and maintenance of good bulls, the keeping of herd books and records of performance, and assisting in the sale of stock. To encourage the movement the French government voted 200,000 francs to be used in promoting the work of the live-stock improvement syndicates in 1912. The syndicates are also permitted to receive subsidies under certain conditions. The appendix contains the rules adopted by some of the syndicates.

**How the sale of live stock is organized in Austria** (*Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intcl.*, 3 (1912), No. 7, pp. 3-12).—This article describes the work of the general federation of the agricultural cooperative societies of Austria in the marketing of live stock for individual breeders.

Reliable agents residing in the principal centers of production are employed to collect the live stock which individuals have for sale and forward it to the "Viehverwertungsstelle" of some city. Here the agents of the federation sell the animals to the best advantage, and after deducting expenses, but without any commission charges, forward to the breeders the returns. This method of marketing enables the isolated breeder to take advantage of the better terms offered by the large markets and thus secure for himself profits which would otherwise go to the middleman. The value of live stock sold in this way increased from about \$37,000 in 1907 to about \$2,635,000 in 1911.

A detailed account of the actual workings of a number of these associations, together with the encouragement given by the State, is also given.

**The German potash industry and potash legislation**, J. SCHÖNEMANN (*Die Deutsche Kali-Industrie und das Kaligesetz. Hannover, 1911, pp. VII+152, pls. 10*).—This publication presents a detailed discussion of the importance of the German potash industry; the motive of legal regulation of the industry; history of the legislation, and its economic significance as applied to the mine owner, manufacturer, dealer or consumer, and laborer; its influences upon foreign countries; and the treatment of contracts with American trusts.

**Agricultural reciprocity between America and China**, G. W. GROFF (*Canton Christian Col., Dept. Agr. Invest. Bul.* 5 [1912], pp. 40, figs. 34).—This bulletin deals with a comparison of American and Chinese agricultural methods, states the opportunity for mutual helpfulness, suggests the field for service, and outlines an organization through which the work may be accomplished.

**The original home of agriculture of the Indo-Germanic people**, R. BRAUNGART (*Die Urheimat der Landwirtschaft aller Indogermanischen Völker. Heidel-*

*berg, 1912, pp. VIII+470, pl. 1, figs. 266*).—A history of the agriculture of the ancient inhabitants of Europe and Asia, presented in the form to support the view that the agriculture of the Indo-Germanic tribes had its origin in central or northern Europe. The work is the result of many years' study of the cultivated plants and primitive farming implements.

**Annual and average production of and international trade in important agricultural products, by countries, R. T. McKENNA** (*U. S. Dept. Agr., Bur. Statis. Circ. 31, pp. 39*).—This circular presents a compilation from the Year-books of this Department of data showing the annual and average production of important agricultural products in the leading agricultural countries, with the percentage each contributes to the total annual production, together with similar data respecting exports and imports of certain agricultural products.

**Crop Reporter** (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 14 (1912), No. 7, pp. 49-56*).—Notes and statistics are here presented showing the acreage and condition of the leading crops in the United States July 1, by States, with comparisons; acreage and estimated production of wheat, rye, barley, and oats in various countries as shown by the report of the International Institute of Agriculture; distribution of the land area in continental United States, 1910; farm value of important products; condition of cereals in various foreign countries June 1; temperature and precipitation statistics; acreage and condition of tobacco by types July 1; monthly receipts and stocks of eggs and poultry in the United States; and the range of prices of agricultural products at important markets; the text of a recent act relating to the issuing of cotton reports; and other data.

**Improving Canadian agriculture, J. W. ROBERTSON** (*Com. Conserv. Canada Rpt., 3 (1912), pp. 89-105*).—Observations are here made regarding systems of agriculture in Canada and methods of improving them, as the result of a survey of 1,212 Canadian farms by the Commission of Conservation, appointed to inquire into and report on questions relating to conservation of soil fertility, agricultural labor, health, and prosperity of the country.

It is noted that a varying number of farms in each of the 9 Provinces investigated reported increases in the yield of crops as compared with 10 years ago except in Manitoba where no farms reported an increase, but 46 out of 100 reported a decided decrease. The general conclusion reached by the commission is that where a systematic rotation of crops prevailed there has been from two to three times the profit to the farmers and a conservation of fertility.

**Agricultural survey [in Canada], 1911, F. C. NUNNICK** (*Com. Conserv. Canada Rpt., 3 (1912), pp. 106-129, table 1, pls. 4*).—A brief summary of the agricultural conditions found in each Province by the Commission of Conservation is here presented, together with tables giving detailed figures relating to conditions found, and a reproduction of the question schedule used in the collection of the information. The following table presents figures relating to the number of farms, acreage, etc., investigated in each Province:

*Number of farms, acreage, etc., investigated in 9 Canadian Provinces.*

	Nova Scotia.	Prince Edward Island.	New Brunswick.	Quebec.	Ontario.	Manitoba.	Saskatchewan.	Alberta.	British Columbia.
No. of farms studied....	100	100	100	200	300	100	87	85	140
Total acreage.....	16,808	10,992	13,991	30,552	33,340	39,999	35,303	22,713	62,428
Field crop acreage.....	5,958	8,220	6,836	19,460	24,634	28,045	24,616	16,222	14,761
Cereal acreage.....	1,072	2,508	1,750	5,640	10,917	26,083	24,149	12,855	3,632
Hoe crop acreage.....	277	516	249	806	3,126	205	.....	89	1,263
Hay and pasture.....	4,609	5,196	4,837	13,014	10,596	1,757	.....	.....	9,846

**Agricultural statistics, 1911.** R. H. REW (*Bd. Agr. and Fisheries [London], Agr. Statis., 46 (1911), No. 4, pp. 275-375, fig. 1*).—This report contains detailed statistics of the imports and exports of agricultural produce into and from the United Kingdom and the returns of the trade in live stock between Great Britain and Ireland in 1911, with comparisons. The total value of the chief kinds of imported food, excluding sugar, rice, and lard, was £149,635,000, as compared with £27,835,000, as the average value for the 7 years 1856-1862. The greatest increase in quantity was meat, the over-sea supply increasing from 5.3 lbs. per head in 1856-1862 to 15.5 lbs. per head in 1905-1911.

**General statistics in France** (*Ann. Statis. [France], 30 (1910), pp. 102-104, 109, 110, 143\*-145\*, 182\*-189\**).—An official report giving detailed statistics regarding number and memberships of professional, industrial, commercial, and agricultural syndicates in France, June 1, 1910. The agricultural syndicates, according to the report, numbered 4,948, with a membership of \$13,038, of which 14,720 were women. There were 77 unions of agricultural syndicates and 4,726 affiliated syndicates, with a membership of 1,067,417.

Other statistics are given as to number and work of mutual agricultural credit banks, together with data pertaining to various crops from 1815 to 1911 in France, including tables which show the area and production of wheat, oats, potatoes, etc., in various other countries from 1850 to 1911.

**[Agricultural statistics of South Australia]**, L. H. SHOLL (*So. Aust. Statis. Dept. Bul. 1, 1912, pp. 16*).—This bulletin presents final results of the cereal, hay, and fodder crops in South Australia for the year 1911.

The total area under cereal cultivation was 2,907,182 acres, of which 2,607,206 acres was in wheat, which gave an average yield of 9.29 bu. per acre, a decrease of 2.28 bu. as compared with the previous year. The total value of the grain, hay, and fodder crops is estimated at £5,410,005.

**[Live stock statistics of South Australia]**, L. H. SHOLL (*So. Aust. Statis. Dept. Bul. 2, 1912, pp. 4*).—In this report is shown the final results of live stock statistics in the various counties and divisions of South Australia for the year 1911. The cattle numbered 393,566, an increase of 8,704 over last year; horses 259,719, an increase of 10,393; sheep 6,171,907, a decrease of 95,570; and dairy cows 121,803, an increase of 2,175. The amount of butter made is reported at 9,694,666 lbs., a decrease of 1,022,820 lbs., and cheese 1,517,561 lbs., a decrease of 278,720 lbs. The butter exported amounted to 2,079,195 lbs., valued at £103,875.

## AGRICULTURAL EDUCATION.

**The educational value of agriculture.** E. BARNES (*Advance print from Nat. Ed. Assoc., Proc. Dept. Superintendence, 1912, pp. 147-150*).—Some of the advantages of instruction in elementary agriculture when well given, according to the author, are as follows: (1) It commands from the start a wide range of the interests most common to children, (2) it forces measures and comparisons, and judgment thereon, upon the child at every turn, (3) it trains a child to be careful, exact, patient, and persistent, (4) it offers in the gardening work all the elementary problems of form, color, and proportion, and so lays the foundations of a sense of beauty, (5) it affords abundant opportunity for emulation and cooperation, and (6) it teaches boys and girls to work. Inasmuch as it discourages pure reasoning, students should also be taught pure mathematics, logic, and languages. The author points out that "our trouble in the past has been that we have tried to take our school children directly into this abstract world of exact thinking and exalted feeling without passing them

through the preliminary stages of concrete experience, elemental virtues, and active self-expressions."

**Report to the forty-seventh general assembly of the State of Illinois** (*Springfield: Ill. Ed. Com., 1911, pp. 126*).—This is a report of the work to date of the Illinois Educational Commission, appointed by the governor in 1907 to examine into the need of changes in the school laws.

Among the recommendations of the commission is a comprehensive plan for providing vocational courses in the public schools of the State. It was also recommended that the high-school curriculum distinctly recognize the vocational needs of the pupil, to the extent of at least one-fourth of the student's time; that the nature-study work of the grades be of such a character as to prepare the child for an intelligent choice of his vocational course; and that schools be advised to ascertain to what extent pupils are engaged in duties outside of school, and in case such duties are definite and regular that proper credit should be given.

**Third annual report of the Congressional district agricultural schools of Georgia**, J. S. STEWART (*Bul. Univ. Ga., 1912, No. 188, pp. 39, figs. 2*).—The attendance for 1911 in the 11 schools was 1,338, representing 110 counties. The farm products for the year amounted to \$33,818. The schools own livestock valued at \$20,828, and farm tools valued at \$8,000.

The majority of the schools now charge less than \$10 a month for board, and require from 20 to 36 hours' work without pay. Additional work is paid for at 10 cents an hour.

**Agricultural education in Canada**, J. K. DOHERTY (*Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 1, pp. 40-45*).—Brief accounts are given of the object and work of the Ontario Agricultural College, the Manitoba Agricultural College, Macdonald College, Saskatchewan University, Nova Scotia Agricultural College, and the Agricultural Institute of Oka, Quebec, and of the college extension work in Ontario.

**Status of agricultural instruction** (*Rap. Trien. Chambres Lég. Min. Agr. et Trac. Pub. [Belgium], 1906-1903, pp. XV111+315*).—This is a report for the years 1906, 1907, and 1908, submitted by the Minister of Agriculture and Public Works to the legislative chambers of Belgium, on the collegiate, secondary, elementary, and itinerant instruction in agriculture, horticulture, and home economics; educational value of agricultural exhibitions; agricultural libraries; and inspection of agricultural instruction in Belgium. In the appendixes detailed information is given concerning the general organization, curriculum, government aid, experiments, faculty, publications, attendance, etc., of each institution under the direction of the department.

**Agricultural instruction in Denmark**, A. M. T. WESTERMANN (*Bul. Mens. Off. Rensciq. Agr. [Paris], 11 (1912), No. 4, pp. 483-489*).—An account is given of the status of agricultural instruction in Denmark in 1909-10, including agricultural apprenticeships, agricultural instruction in the 58 secondary schools, itinerant agricultural instruction, agricultural instruction for soldiers, and higher agricultural instruction at the Royal Agricultural and Veterinary Institute at Copenhagen.

**Report of the Alnarp Agricultural and Dairy Institute, 1911** (*Ber. Verks. Alnarps Landtbr. och Mejeri Inst., 1911, pp. 32, pl. 1*).—This is a report on the work of the institute during the year.

**Horticultural instruction in the Netherlands**, K. SCHECHNER (*Land u. Forstv. Unterrichts. Ztg., 25 (1911), No. 3-4, pp. 316-319*).—The author gives an account of the system of horticultural instruction in the Netherlands, including higher instruction at the Royal Agricultural, Horticultural, and Forestry High School at Wageningen; secondary instruction at the horticul-

tural winter schools at Aalsmeer, Boskoop, Naaldwijk, and Tiel, and the Girard Adriaan van Swieten Forestry School at Fredericksoord; elementary instruction in special winter courses; special courses for adults; and courses for public-school teachers.

**A new feature of agricultural instruction in Prussia** (*Land u. Forstw. Unterrichts. Ztg.*, 25 (1911), No. 3-4, pp. 313-315).—An account is given of the object, organization, admission requirements, curriculum, etc., of the seminars for farmers being established by the chambers of agriculture in Prussia under the control of the Ministry of Agriculture, Domains, and Forests.

**Statistics of education in the Kingdom of Wurttemberg for 1910** (*Statist. Unterr. u. Erziehungsw. Kgr. Württemb.*, 1910, pp. 70).—This publication includes statistics of the agricultural institutions in the Kingdom of Wurttemberg, viz, the agricultural high school and stations at Hohenheim, veterinary high school at Stuttgart, the farm schools at Ellwangen, Kirchberg, and Ochsenhausen, the viticultural school at Weinsberg, 8 agricultural winter schools, agricultural continuation schools, short courses, etc.

[**Agricultural and forestry education in Austria and other countries**] (*Land u. Forstw. Unterrichts. Ztg.*, 25 (1911), No. 3-4, pp. 1+221-381).—In addition to several articles abstracted elsewhere in this issue, this report includes the following: The Problems of Moral and Religious Training in Elementary Forestry Instruction, by K. Pusch; Equipment and Profitableness of the Farms of Agricultural Education Institutions in Austria; Review of Agricultural Literature and of Annual Reports of Agricultural and Forestry Education Institutions for 1910-11; and miscellaneous notes.

**The objects of the experiment farm of the Royal Imperial Agricultural High School, ADOLF RITTER VON LIEBENBERG** (*Land u. Forstw. Unterrichts. Ztg.*, 25 (1911), No. 3-4, pp. 229-240).—The author discusses the objects and work of the experiment farm of the Vienna agricultural high school, which is located at Grossenzersdorf, from the standpoint of a complete experimental farm as distinguished from the demonstration fields of the majority of schools.

**A thirty-year cycle in agricultural school existence, F. KOZESCHNIK** (*Land u. Forstw. Unterrichts. Ztg.*, 25 (1911), No. 3-4, pp. 254-269).—The author gives an account of the beginnings of the farm and viticultural school at Feldsberg, in Lower Austria, as showing the difficulties and requirements of teachers at that time.

**The rural continuation school for boys and girls, KERSCHENSTEINER** (*Arb. Deut. Landw. Gesell.*, 1910, No. 167, pp. 130-195).—Of the 3 views current for the development of the rural continuation school, viz, (1) that it should continue subjects of instruction given in the public elementary schools, (2) that it should give theoretical instruction in agriculture, and (3) that it should give practical instruction in agricultural subjects particularly adapted to its locality, the author favors the latter and presents reasons therefor. An appendix gives 32 suggestions concerning the organization of rural continuation schools and the assistance of itinerant instructors in their development.

**Announcement of farmers' short courses for 1912 at the University Farm, Davis, Cal.** (*California Sta. Circ.* 78, pp. 23, figs. 12).

## NOTES.

---

**Alabama Canebrake Station.**—W. G. Little, of Livingston, has succeeded E. B. Martin as a member of the board of control.

**Arizona Station.**—Dr. O. C. Bartlett has been appointed assistant state entomologist. A. L. Enger has succeeded F. C. Kelton as assistant engineer.

**Arkansas University and Station.**—H. E. Truax has been appointed assistant plant pathologist, and has entered upon his duties.

**California University and Station.**—The new agricultural building was dedicated November 20, with addresses by President Wheeler, ex-Dean Wickson, Dean Hunt, Prof. F. R. Marshall, and others. During the exercises Dr. Hunt was formally installed as dean and director, and a bust of Dr. E. W. Hilgard was presented by the president of the agricultural club, a student organization.

Dr. Le Roy Anderson has been appointed professor of dairy industry, and Harry S. Baird instructor in dairying at Davis.

**Connecticut State Station.**—W. O. Filley has been appointed state and station forester, vice S. N. Spring, whose resignation has been previously noted; and A. E. Moss has been appointed assistant station forester. R. B. Roe, assistant chemist, resigned October 1 to engage in commercial work.

**Connecticut Storrs Station.**—Director L. A. Clinton has resigned to accept a position with this Department in charge of the farm management investigations in New York, New Jersey, Pennsylvania, and New England.

**Florida University and Station.**—A monthly grant has been made by the Florida Citrus Exchange for investigating the changes in the sugar and acid content of citrus fruits. A citrus seminar was held at the station October 8 to 10, with an attendance of about 60, for the discussion of the subjects under investigation.

C. L. Willoughby, formerly of the Georgia Station, has been appointed head of the department of animal husbandry and dairying in the university, and James H. Carpenter has been appointed assistant chemist.

**Idaho University and Station.**—The division of agronomy has been subdivided into a department of field crops and farm management and a department of soils and soil physics, under the direction respectively of Frank L. Kennard as associate professor of field crops and farm management, and Dr. P. P. Peterson, of the Wisconsin Station, who has been appointed professor of soils and soil physics.

Other appointments include Orlo A. Pratt as assistant in plant pathology in the university and assistant plant pathologist in the station; John C. Kinzer, a graduate of the university, as assistant animal husbandman in the station; Earl C. Hall, a 1912 graduate of the university, as agricultural field agent for Bonner County in cooperation with this Department and with headquarters at Sandpoint; and George B. Caine as agricultural and dairy field agent for Lincoln County, in cooperation with this Department.

**Illinois University and Station.**—A new \$50,000 glass house for the college and station is now under construction. One portion of it will be used for

floriculture and another for plant breeding and vegetable gardening. The former horticultural greenhouse has been rebuilt for work in agronomy. The central portion of the stock judging pavilion is to be completed in the near future.

A. L. Whiting, who received the degree of Ph. D. from the university in June, has been appointed instructor in soil biology; O. M. Allyn assistant in crop production, vice Arthur Lambriek, resigned to become manager of an estate; and S. J. Bole instructor in pomology and assistant in plant breeding.

**Purdue University.**—H. B. Switzer, a 1912 graduate of the college of agriculture, has been appointed assistant in dairy bacteriology.

**Iowa College.**—The veterinary buildings under construction have been completed at a cost of \$200,000. The group consists of 5 buildings, inclosing an inner court 163 by 106 feet, and contains an administration building, one for pathology and bacteriology, one for physiology and pharmacy, a clinic and hospital building, and an anatomy building. Eventually a sixth building for research and experimental work is to be included.

It is expected that 103 extension short courses will be held in the State during the coming season. New courses have been added in poultry husbandry, bookkeeping, veterinary science, entomology, and concrete construction.

E. F. Ferrin has accepted the assistant professorship of animal husbandry.

**Kansas College and Station.**—T. J. Headlee has been appointed state entomologist of New Jersey and has been succeeded by G. A. Dean in entomology and Dr. R. K. Nabours in zoology. Other appointments include Edwin C. Johnson, of Minnesota University, as superintendent of farmers' institutes; C. D. Steiner in charge of boys' clubs; G. O. Greene, specialist in horticulture in the extension department; Dr. C. W. McCampbell as assistant professor of animal husbandry and assistant in animal husbandry; E. A. Langworthy in charge of the feeding stuffs inspection; C. M. Vestal assistant in animal husbandry; Dr. Maurice C. Tanquary assistant in entomology; and R. A. Jehle instructor in botany.

Recent resignations include P. N. Flint as assistant professor of animal husbandry, Dr. N. E. Stevens as instructor in botany and assistant plant pathologist, and C. V. Holsinger as horticulturist of the extension department.

**Kentucky University and Station.**—Recent appointments include the following: In the university, James A. Farra as assistant professor of farm mechanics, R. E. Knapp as assistant professor of bacteriology, Ralph Kenney as instructor in soils, and H. B. Hendricks and J. H. Carmody in extension work, the former in agronomy and the latter in horticulture; and in the station James E. Mastin, James S. McHargue, and G. D. Buckner as assistant chemists, Walter Scheppleman and E. F. Worthington as food inspectors, R. L. Pontius and L. W. McElyea as assistant veterinarians, and W. D. Nicholls and G. C. Routt as assistant animal husbandmen.

**Louisiana University.**—Elizabeth B. Kelley has been appointed professor of home economics in the extension division.

**Maine Station.**—Dr. O. A. Johannsen has resigned to become assistant professor of biology in Cornell University.

**Maryland College.**—The main administration building and the dormitory were destroyed by fire November 29, causing an estimated loss of \$270,000, partially covered by insurance. President R. W. Silvester has resigned on account of ill health and has been appointed president emeritus and librarian. Prof. T. H. Spence has been designated acting president.

**Massachusetts College and Station.**—The apple packing team won first place in the intercollegiate contest held in Boston, November 8, with New Hampshire second and Vermont third. In the apple judging contest New Hampshire was

first, Massachusetts second, and Vermont third. George R. Pierce has resigned as assistant chemist in the station to accept a commercial position in Cuba, and B. G. Southwick has resigned as secretary to the director to become manager of a farm in Pennsylvania.

**Michigan College.**—C. E. Newlander has been appointed instructor in dairy manufactures and has entered upon his duties. Joseph C. Bock, instructor in chemistry, has been appointed chemist in the nutrition laboratory of the Carnegie Institution of Washington.

**Minnesota University and Station.**—During the past summer the university carried out a program of lectures and demonstrations, interspersed with entertainments, over the State, which was divided into three circuits of six accessible centers each. Each circuit received a week's attention, and through the use of six groups of lecturers each center in the circuit had the advantage of the entire week's program. The program included a farmers' day, a town and country day, business men's day, a home welfare day, a public health day, and an art and literature day. The expenses were met by an advance guaranty from each community of \$300.

One feature of the program was the farmer boys' camps, held at most of the centers. The camp leader drilled his boys in farm mechanics, took them to farms and gave them lessons in stock judging, and led them in other ways. The object of this university week was to bring the people of town and country together to receive instruction of a kind "to increase the attractiveness, dignity, and profit of life on the farm and in the town."

Recent appointments include Arthur C. Smith as poultryman; E. W. Major, of the University of California, as associate professor of animal nutrition and assistant dairy husbandman; C. W. Howard, of the Rockefeller Institute, as instructor in entomology and assistant entomologist; Masaji Kugimoto as assistant in animal nutrition; and Mark J. Thompson in charge of the farm at Duluth.

Plans have been approved for a dairy laboratory at the North Central Farm at Grand Rapids. The Cloquet substation is to be maintained on a cooperative basis with this Department.

**Missouri University and Station.**—A course in rural economics is being offered for the first time in connection with the regular course in agriculture. The work is being given by S. D. Gromer, recently appointed secretary of the university extension service. The first term of the two-year winter course in agriculture opened with an enrollment of 183 students.

The station has begun to issue a series of numbered press bulletins in addition to the press notices previously sent out.

John A. Ferguson, professor of forestry, has accepted a similar position at the Pennsylvania College, this taking effect January 1, 1913. Recent appointments include Ernest C. Pegg as instructor in forestry, and the following assistants in the station: L. B. Burke in animal husbandry, Ray Evans and M. A. R. Kelly in agronomy, William Regan in dairy husbandry, and T. T. Tucker in veterinary science. C. B. Hutchison, assistant professor of agronomy, has been granted a year's leave of absence to take up graduate work at Cornell University.

**Nebraska University and Station.**—Recent appointments include H. E. Bradford as principal of the school of agriculture, J. R. Cooper, of the Kansas College, as assistant professor of horticulture and assistant horticulturist, Miss Alice M. Loomis, of the Wisconsin University, as professor of home economics, and Miss Anna Olsen as adjunct professor of home economics.

**New Hampshire College.**—W. R. Wilson, a 1912 graduate of Cornell University, has been appointed instructor in dairying.

**New Mexico College and Station.**—An entirely new board of regents has been appointed, consisting of J. H. Paxton president, M. O. Llewellyn secretary and treasurer, A. H. Hudspeth, R. R. Larkin, and F. E. Lester, with Governor W. C. MacDonald and Hon. A. N. White, state superintendent of public instruction, as ex-officio members. R. E. Willard has resigned as assistant professor of agronomy to accept a position with the Farm Management Investigations of this Department.

The horticultural and agronomy departments have instituted cooperative experiments in the breeding of onion seed.

**Cornell University and Station.**—The new department of forestry is offering a full professional course of 5 years, leading to the degree of B. S. at the end of the fourth year and that of M. S. a year later. Work for the Ph. D. degree is also offered, as well as a one-year course in the elements of forestry.

The horticultural library of the late Professor Craig has been donated to the horticultural department of the college of agriculture. The collection includes over 3,000 volumes, being especially rich in the subject of pomology.

Dr. H. J. Webber has accepted a position with the University of California as professor of plant breeding, director of the citrus substation at Riverside, and dean of the proposed school of tropical agriculture. Robert Matheson has been appointed entomologist for the Province of Nova Scotia and professor of zoology at the Nova Scotia Agricultural College.

**North Carolina College Station.**—Joseph F. Brewster (Ph. D. Berlin, 1912) has been appointed assistant chemist.

**Ohio State University.**—The new poultry plant was formally opened October 12. The equipment comprises an instruction building and incubator house, a laying house 126 feet long, and a brooder house. At present over 1,000 fowls are being kept. A total of 18 students are registered in the course.

J. H. Gourley, of the extension department, has accepted the position of head of the horticultural department at the New Hampshire College and Station. Recent appointments include Donald J. Kays, a 1912 graduate of the University of Illinois; William Hislop (M. S. Kansas College, 1912), and Gilbert Gusler (Ohio, 1912) as instructors in animal husbandry; R. B. Stolz (Ohio, 1912) as instructor in dairy husbandry; M. C. Sewell as instructor in soils; and Ralph R. Jeffries as assistant in horticulture.

**Oklahoma College and Station.**—The new college year opened September 2 with an enrollment of over 700 students in regular courses, and this will probably reach 1,200. Many changes in the buildings and the completion of the new engineering building serve to facilitate the work of both the college and station. The department of agronomy is now conveniently housed in its own building, with ample room for soil work, grain judging, and farm machinery studies. The chemical department of the station has moved to the chemistry building, thus bringing all the work in chemistry under one roof. The vaccine and Bermuda grass work of the station have been transferred to the departments of veterinary science and animal husbandry respectively of the college.

Ray Painter has been appointed assistant in entomology.

**Oregon College and Station.**—M. M. McCool (Ph. D. Cornell, 1912) has been appointed assistant professor of soils and assistant agronomist, E. M. D. Brocker, of Purdue University, instructor in farm management, and W. L. Powers assistant professor of irrigation and drainage and superintendent of the irrigation demonstration farm.

**Pennsylvania College and Station.**—W. G. Ross has resigned as assistant professor of agronomy to accept the position of superintendent of farms for the Western Penitentiary of the State, and is succeeded by W. H. Darst of the extension department of Ohio State University. Joseph F. Cox (Ohio, 1912)

has succeeded W. W. Reitz as assistant in agriculture. J. D. Harlan, a 1912 graduate of the college, has been appointed assistant in experimental agriculture. E. L. Anthony assistant in dairy husbandry, and David E. Warner assistant in poultry husbandry.

**Tennessee University and Station.**—About 100 students are enrolled in the agricultural course, constituting the largest attendance thus far registered. A series of 8 short courses of one week's duration, to be held at various points in the State, was begun October 28.

Drainage investigations upon three distinct types of soil in the State to depths of from 1 to 6 feet, and treatment with lime and manure, are being inaugurated. The station and its substation at Jackson are to feed experimentally over 150 steers this winter.

J. E. Toomer, assistant chemist of the station, has resigned and has been succeeded by L. G. Willis of the Pennsylvania Station.

**Vermont University.**—R. T. Burdick (Cornell 1912) has been appointed instructor in agronomy.

**Washington College and Station.**—Ten extension schools are to be held this year. Dr. R. Kent Beattie has resigned as professor of botany and bacteriology to accept a position with the Forest Pathological Investigations of this Department.

**Wyoming University and Station.**—The trustees have authorized the construction of a \$100,000 building to house the agricultural instruction in the university and the laboratories and offices of the station. The building is to be of fire-proof construction, with 3 stories and full basement. The basement will be a laboratory floor for agronomy, entomology, farm mechanics, etc., and will contain an agricultural museum. The main floor will house the offices of the director, animal husbandman, agronomist, and the library. A lecture room will be provided upon the second floor to accommodate 150 students, as well as laboratories for research, chemistry, biology, parasitology, and pathology. The third story will be occupied by the chemical department for instruction and the work of the pure food commission.

**Tenth International Congress of Agriculture.**—The next meeting of this congress is announced for June 8 to 13, 1913, in connection with the International Exposition at Ghent, Belgium. The congress will be organized into sections of (1) rural economy, (2) the science of agriculture, culture of special crops, and agricultural education, (3) cattle breeding, (4) agricultural engineering, and (5) forestry. Papers should be submitted by January 1, 1913, and may be in French, German, or English and should be accompanied by brief abstracts in French. Mr. Jules Maenhaut, president of the Société Centrale d'Agriculture of Belgium, is president of the executive committee, and Mr. Paul de Vuyst, director-general of the Rural Office, 22 Avenue des Germaines, Brussels, is general secretary.

The third International Congress of the Associations of Agricultural Women will be held at Ghent, June 13 to 15. This congress will be organized into three sections, namely, agricultural women's associations, the professional rôle of agricultural women, and agricultural women in the rôle of the mother and the manager. Mrs. John T. Burns, Lethbridge, Alberta, is representative from North America. Miss Van Aarschot, 38 Rue du Pépin, Brussels, is treasurer, and applications for membership should be sent to her.

The second International Congress of Home Training will follow these meetings, on June 15 to 17.

## CONTENTS OF VOL. XXVII, NO. 8.

	Page.
Editorial notes:	
The semicentennial of the National Department of Agriculture.....	701
The quarter centennial of the experiment station system.....	708
Recent work in agricultural science.....	712
Notes.....	799

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Phytin and pyrophosphoric acid esters of inosit, II, Anderson.....	712
Experiments with the castor bean lipase, Falk and Nelson.....	712
Rôle of electrolytes in the action of ferments of animal origin, Bierry.....	712
The hydrolytic action of hydrogen peroxid, Neuberg and Miura.....	712
Ignition of precipitates without the use of the blast lamp, Walker and Wilson.....	713
Precipitating agents for amino acids, Neuberg and Kerb.....	713
A delicate method for determining minute quantities of chlorophyll, Jacobson.....	713
Colorimetric determination of phosphoric acid in arable soils, Herrera.....	713
Determination of moisture in cereals and cereal products, Fernet.....	713
The determination of sugar in natural substances, Neuberg and Ishida.....	714
The composition of Fehling's solution as used at the present time, Lüning....	714
The amount of formic acid in honey, Fincke.....	714
The analysis of vinegar, Paterson.....	714
Analysis of paprika, De Sigmond and Vuk.....	715
The detection of benzoic acid in foods and condiments, Polenske.....	715
Determination of the total solids in milk, Splittgerber.....	715
The chlorin content of milk, Poetschke.....	715
Determining fat in milk according to Röse-Gottlieb method, Rupp and Müller.....	715

	Page.
The detection of coconut fat in butter and lard, Polenske.....	716
Determination of fat in feeds by extracting in the cold, Grimme.....	716
Grading rosin at the still, Veitch and Sammet.....	716
Oil from plants belonging to the order Papilionaceæ, Grimme.....	716
Heat of combustion of bagasse from Hawaiian cane, Norris.....	717
Sisal and the utilization of sisal waste, Wilcox and McGeorge.....	717
Report of the Pommritz Experiment Station, 1911, Loges.....	718
International catalogue of scientific literature. D—Chemistry.....	718

## METEOROLOGY—WATER.

The correlation between sunspots and the weather, Gockel.....	718
[Weather observations], Blake, Halsted et al.....	718
Weather report, Day.....	719
Swedish meteorological observations, 1911, Hamberg.....	719
Duration of sunshine and insolation at Stockholm and Häfringe, Westman.....	719
Frosts in New York, Wilson.....	719
Electric Niagaras and recent storms, Laforest.....	719
Well water, Harcourt.....	719

## SOILS—FERTILIZERS.

The soils of Oregon, Bradley.....	719
Sandy soils of western and northern Michigan, Jeffery.....	720
Results of chemical studies of the cane soils of Java, Marr.....	720
Soil mapping and geological-agronomic maps, Koehne.....	720
The Mangum terrace in its relation to efficient farm management, Cates.....	720
Bacteriological studies of field soils.—I, The effects of lime, Brown.....	720
Bacteriological studies of field soils.—I, The effects of liming, Brown.....	720
Bacterial activities in frozen soils, Brown and Smith.....	720
The law of minimum and the law of physiological ratios, Mazé.....	721
The law of minimum, Mitscherlich, Pfeiffer, and Fröhlich.....	721
Ammonia and nitrate formation in soils, Lipman, Brown, and Owen.....	721
Influence of sugar on productivity of soils, Pfeiffer and Blanck.....	722
Action of alumina gel on assimilation of phosphoric acid, Pfeiffer and Blanck.....	722
Effect of heating and antiseptics on fertilizing ingredients, Jensen.....	722
Influence of micro-organisms in night soil on the fertilizing effect, Masoni.....	722
Report of Leteensuu Moor Experiment Station, 1912, Simola.....	723
Report of the South Oesterbotten Moor Experiment Station, 1912, Rautakoski.....	723
The nitrate of soda industry of Chile, Ossa.....	723
The use of nitrate of soda in commercial fertilizers, Cathcart.....	723
Availability of nitrogenous materials found by ammonification, Lipman et al.....	723
Experiments with new nitrogenous fertilizers, 1908-1911, Rhodin.....	724
Destruction of wild mustard by means of lime nitrogen, Lipschütz.....	724
Seaweed, potash, and iodine: A criticism, Knudsen.....	724
The extraction of potash and alumina from feldspar, Foote and Scholes.....	724
Production of available potash from natural silicates, Cushman and Coggeshall.....	724
Pot experiments with different potash minerals, Prishnikov.....	724
To what extent can potash of fine-ground feldspar be utilized? von Feilitzen.....	725
Comparative tests of phonolite, 40 per cent potassium salts, and kainit, Öhme.....	725
Thomas phosphate meal, Hissink.....	725
The agricultural value of electric slag, De Molinari and Ligot.....	725
Assimilation of phosphatic fertilizers in rotation, Müntz and Gaudechon.....	725
The assimilation of phosphoric acid by plants, Müntz and Gaudechon.....	725
Effect of cow dung on availability of rock phosphate, Hartwell and Pember.....	726
Action of calcium carbonate in fertilizing oats with phosphate, Simmermacher.....	726
The mechanism and fertilizing action of sulphur, Boullanger and Dugardin.....	726
Action of manganese oxid on nitrogenous compounds, Leoncini and Pieri.....	726
Indigenous manures of South India and their application, Harrison.....	727
Comparative trials of hand peat-litter machines.....	727
Fertilizer statistics, Zolla.....	727
Fertilizers, Rose and Heimbürger.....	727
Fertilizer analyses, McDonnell et al.....	727
Inspection of commercial fertilizers, season 1911 and 1912.....	727
List of fertilizer manufacturers and importers.....	727
The lime inspection law of Maryland.....	727

## AGRICULTURAL BOTANY.

	Page.
Studies on fungi for beginners.—II, Microscopic fungi, Lindau.....	727
Bacteria, yeasts, and molds in the home, Conn.....	727
A laboratory guide in soil bacteriology, Lipman and Brown.....	728
Fungus flora of the soil, Jensen.....	728
Bacteria and other fungi in relation to the soil, Rivas.....	728
Studies on <i>Penicillium puberulum</i> , Alsberg and Black.....	729
Some conditions influencing nitrogen fixation by aerobic organisms, Bottomley.....	729
Influence of temperature on the zoospores of <i>Chlamydomonas</i> , Desroche.....	729
Studies in seeds and fruits, Guppy.....	729
Influence of organic acids and glucose on respiration of seeds, Promsy.....	729
Tannin in the seed coats of barley, Reichard.....	730
Pentosans and methylpentosans in <i>Glycine hispida</i> and <i>Phaseolus vulgaris</i> , Miyake.....	730
The artificial nourishment of seedlings, Zaleski and Tutorski.....	730
Effect of asparagin on absorption and growth in wheat, Skinner and Beattie.....	731
The carbohydrates and nitrogen-containing bodies in grape leaves, Deleano.....	731
Phosphoric acid and nitrogen in alcoholic extract of leaves, Seissl.....	731
Influence of phosphates on post-mortem respiration, Zaleski and Marx.....	731
Contribution to the study of circulation. Studies on the sweet potato, Groth.....	731
The stomatograph, Balls.....	732
Photosynthesis and stomatal aperture, Balls.....	732
Reversible changes in permeability produced by electrolytes, Osterhout.....	732
The oxidases of <i>Cytisus adami</i> , Keeble and Armstrong.....	733
Primary color factors of <i>Lychnis</i> and color inhibitors of <i>Papaver rhoeas</i> , Shull.....	733
Cell number in the fruit of the prairie berry, Groth.....	733
Observations concerning evolution, Cockayne.....	733

## FIELD CROPS.

[Field husbandry experiments], Howitt and Zavitz.....	733
[Forage and cover crops], Minkler.....	736
The seed-corn situation, Hartley.....	736
Inheritance in corn, Hayes.....	737
Results of cotton experiments in 1911, Cook.....	737
Cotton crop of the United States, 1790-1911, Holmes.....	738
Hop crop of the United States, 1790-1911, Holmes.....	738

# EXPERIMENT STATION RECORD.

---

VOL. XXVII.

DECEMBER, 1912.

No. 8.

Provision for aiding and strengthening the great national industry of agriculture through a central agency was slow in coming in the United States. With a separateness which was long characteristic the States were left to their own devices, and it was not conceived to be the policy of the General Government to concern itself with the subject. Its vast public domain, much of which was then considered useless for agriculture, was in charge of a land office whose functions were restricted to its survey and record and disposal under federal laws.

As early as 1796 the suggestion of federal aid for the promotion of agriculture was made by President George Washington, who laid before Congress a plan for an agency modeled after the British Board of Agriculture, of which he was an honorary member. But Congress failed to act on this suggestion, as it did on a similar proposal which came from the Agricultural Society of Berkley, Mass., in 1817.

In the course of time, however, the use of public funds for agricultural work began to be practiced, plants, seeds and animals being introduced through the Consular Service and turned over for distribution to the Patent Office, which was then under the State Department. When Henry L. Ellsworth, a practical Connecticut farmer, became Commissioner of Patents in 1836, he gave special attention to the distribution of seeds and plants, and in 1839 he secured a Congressional appropriation of \$1,000 "for the purpose of collecting and distributing seeds, prosecuting agricultural investigations, and procuring agricultural statistics."

Commissioner Ellsworth gave in his report for 1842 a prophetic view of what the application of science would mean to agricultural production. But there were many doubters, not only of the value of science as applied to agriculture, but also of the desirability of government aid to agriculture. This is evidenced by fluctuating appropriations, which at times were cut off entirely. After the Patent Office was transferred to the Interior Department, in 1849, the appropriations increased. a chemist, botanist, and statistician were employed, meteorological data were regularly furnished by the Smith-

sonian Institution, and information on many agricultural subjects was published in the annual reports. In this period the principle was gradually established of governmental promotion of agriculture, not only through the distribution of seeds, but through the employment of science.

With the coming of Lincoln's administration a plan was put forward by David P. Holloway, Commissioner of Patents, for the creation of "a department of the productive arts." Congress adopted a portion of the commissioner's plan and established a department of agriculture, President Lincoln signing the act May 15, 1862. The new department was formally organized on July first of that year, in the rooms of the Patent Office previously occupied by the agricultural division; and on the following day, July 2, President Lincoln signed the Morrill Act.

Thus it came about that the provision of a national agency for agriculture and of federal aid for the establishment of agricultural education, both of which had long been urged, were realized at the same time, and at a time when the country was in the midst of its mighty struggle for union. It is worthy of note also that on May 20 of that year President Lincoln set his approval on the Homestead Act, culminating an agitation for the settling of the public lands which had been a national issue for ten years previous. It is remarkable that these three events, which have been of such fundamental importance to the agriculture of this country, should all have been culminated within a period of less than six weeks.

From these small and uncertain beginnings, there has resulted in the period of fifty years since the Department of Agriculture was formally established an organization for the administration of law, prosecution of research, and the collection and dissemination of knowledge "the like of which is unknown in any other country or any other time."

The history of the rise of the Department through successive commissioners and secretaries, its elevation to the first rank in the executive branch of the Government in 1888, and its present magnitude and scope, were sketched in the interesting address of Dr. A. C. True at the Atlanta convention of the Association of American Agricultural Colleges and Experiment Stations in November. It was the only observance of this important anniversary. Anniversaries of events of far less import to the American people have been observed in a national way, in a manner to draw public attention to them and emphasize their epoch-making character.

Appreciation of the Department's work and position has come mainly in quite recent years. Until then it was known to many as an agency for the distribution of free seeds, and it had little standing as an institution for agricultural investigation. Its larger growth

is a notable triumph of agricultural science. Nothing else could have given it the dignified standing and the confidence which it now enjoys. The demonstration of science as the fundamental basis of agriculture, of its ability to cast aside the cloak of tradition and superstition and mystery which enveloped it, and to provide an intelligent and reasoning basis for practice, has placed agriculture as an industry on a very different footing in the eyes of the people, as it has also the institutions representing it. Nothing has done so much to impress upon the public the intimate and helpful relation of science to daily life, to educate it to the belief in science as something very real and essential and for universal use, rather than something abstract and incomprehensible and for the pursuit of the few.

In a recent address Dr. David Starr Jordan expressed some thoughts which are well worth considering in this connection, for, although he was speaking primarily of medicine, his deductions are especially applicable to the subject under discussion. After laying down the principle that all art is based on science, and defining science as "human experience tested and set in order," he said:

"Art is knowledge in action, and art which is not based on knowledge becomes a mystery or a trade. The practice of medicine [or agriculture] through the ages has been one or the other or both. It is a trade when the physician's [farmer's] apprentice follows his master about, learns his ways, his prescriptions, and his professional dignity. It is a mystery when practice is based on some theory . . . which goes outside of human experience for its justification. Science is alike to all men who have grasped its data and its conclusions. Art will vary with the personality of the individual who practices it."

Agriculture and the practice of farming have passed through the stage of mystery to that of a trade with professional aspects. Modern scientific agriculture aims to replace tradition with well-established facts. While the art varies with the individual who practices, it is now based on knowledge, i. e., on experience viewed in the light of science. This is its essential characteristic, and the ability to call science into the service of agriculture is a modern accomplishment.

The limitations of experience unaided, and its inadequacy to progress, were well set forth by Dr. H. C. White in his Atlanta address on the American Experiment Stations. The application of original investigation to supplement and extend the experience and observations of daily life marked a new era in the acquisition of knowledge.

Dr. White said: "When Patrick Henry declared that he knew of no lamp by which to guide his feet but that of experience, he spake as a man of the eighteenth century and those which had gone before. For untold centuries individual and traditional experience was counted the safest if not the only guide to conduct. In the great industry of agriculture, in which men had been engaged since the

beginning of human history, experience in like manner had been the school in which instruction had been sought for proficiency in the art and improvement of its processes. The value of experience surely is not to be disclaimed. On the contrary it is a very efficient corrective of error, and men do well to maintain its historic continuity for the avoidance of fault and the elimination of blunder.

“ But while experience may be safe, it is after all but an unintelligent and unprogressive monitor. Certainly in the case of agriculture it has proven its inadequacy to progress. For it may be doubted if agricultural practice or agricultural production in Europe in the eighteenth century were in any large degree superior to those of ancient Babylonia, Egypt, Greece, or Rome. It was only when the truly scientific spirit of inquiry into the causes and reasons of phenomena was loosened upon the world that conduct and practice could be based upon an illuminating knowledge and no longer guided by a blind experience.”

There is little in mere handicraft that can be taught; it must mostly be acquired by experience. Hence the development of such agencies as the agricultural colleges and the Department of Agriculture waited largely on the development of the scientific stage and the explanation of the principles involved. With the application of science and its dissemination, all of these agencies grew in power and resources and size, so that in a remarkable degree they are to be regarded as products of their own activities. The great industry of agriculture has developed with them and very largely as a result of them, and to them is unmistakably due the present position of agriculture as an industry and its efficiency as an occupation.

But there were other conditions in this country which retarded for a time the higher development of agriculture and had a great influence on the progress of these agricultural institutions. Among these were the operations of the Homestead Act, which, as we have seen, came into effect at the same time that the Department and the agricultural colleges were provided for. Other conditions were economic in their nature, and these we are still struggling with.

The Homestead Act promoted on a vast scale the rapid expansion of our agriculture, causing the occupation of the available farm land in a half century and distributing this land among millions of small proprietors. This brought about the production of enormous wealth as the basis for the development of commerce, manufacturing, education and social life. It broadened our more conservative and substantial electorate to such an extent as to enable us to meet the problems arising from vast combinations of capital and labor, so that today we have a fair opportunity for their successful solution.

Looked at from another angle, the Homestead Act brought about conditions which prevented for many years the proper development

of agricultural education in our colleges and schools, and hindered the progress of the Department of Agriculture and the experiment stations. As long as there was plenty of free land and agriculture was being spread out by the simplest methods beyond the immediate needs of the nation, although the aggregate of agricultural production greatly increased, the price of agricultural products constantly tended to fall below the level of profit. Agriculture thus became a backward and depressed industry. The generation of pioneer farmers who had rushed in so eagerly to acquire the free lands became disgusted with the financial outcome and outlook of this business, and sought every avenue of escape from it for their children. Hence the agricultural colleges, begun with much enthusiasm, found little support from the farmers, and after a time began to lose even the meager number of students at first attracted to them.

The Department of Agriculture and the early experiment stations had little encouragement to collect the knowledge on which alone efficient courses in agriculture could be constructed, and remained in a weak and neglected condition. Fortunately there were leaders who saw that this condition of affairs could not last, and that the time would come when the farmers would need help and be eager to receive it. The passage of the Hatch Act, twenty-five years ago, marks the turning of the tide.

In commenting on the change of conditions which has come with passage of years, Dr. True said:

“From being a simple and depressed industry, agriculture is becoming a highly complicated and progressive industry. The universal use of machinery, the necessary changes in methods, crops, and animal husbandry, to meet the new and varied demands of different regions, have caused an unparalleled reorganization of agricultural industries. The many successful applications of science to agriculture, and the evident need of technical education in agricultural science and practice, have caused the establishment in the United States of the most comprehensive and far-reaching system of agricultural research and education ever devised.”

The Department is approaching the close of four successive administrations under the same guiding hand, a period of sixteen years of marvelous growth and development which have far surpassed the combined product of all the previous years. Some of the facts of this growth are brought together in the last annual report of the Secretary of Agriculture, in a retrospect which furnishes a basis for measuring the present scope and diversity of this national agency. These are only faintly indicated by its present income of \$24,743,044 and its force of 13,858 employees.

The present functions of the Department may be broadly classified as (1) administrative, (2) advisory, (3) investigational, (4) informational, and (5) educational. These have been so far developed and expanded that the Department's business vitally affects the daily life of all our people.

Under administrative duties are included those relating to the enforcement of the meat inspection, carried on at nearly one thousand establishments in two hundred and fifty-nine cities and towns; the inspection of foods and drugs, insecticides and fungicides, with regard to both domestic and imported products, which is conducted through the laboratory of the Bureau of Chemistry at Washington and its twenty-five branch laboratories throughout the country; the control and quarantine rendered necessary by sheep and cattle diseases and the inspection of cattle-carrying vessels; the management of the national forests, embracing one hundred and eighty-five million acres, or nearly three hundred thousand square miles of territory; the regulation of interstate commerce of game animals and the control of the importation of noxious and other animals; the Congressional seed distribution; the supervision of the federal funds granted to the state experiment stations; and the direct management of stations in Alaska, Hawaii, Porto Rico, and Guam.

In its advisory capacity, the Department conducts a vast and varied correspondence. Besides this there are some large operations which have in them an important advisory factor. Such, for example, are the daily weather forecasts, the monthly crop reports, the national soil survey, and the cooperative farm demonstration work. Many agents of the Department are now giving much of their time to personally advising the farmers in the districts where they are located. Notable examples of this are the services of the Department's road, irrigation, and drainage engineers. In a similar way this Office has a broad influence on the development of the agricultural colleges, schools, and experiment stations.

The technical, scientific, and practical investigations of the Department now constitute a large share of its business and cover a very wide range. All of the bureaus are engaged in this work, and their projects cover practically every department of agricultural inquiry. They include laboratory investigations in the various sciences bearing on agricultural problems, field experiments in many States and Territories, studies of natural conditions and agricultural possibilities on a large scale, the exploration of foreign countries for plants, beneficial insects, etc., the devising of means to defend the farmer against flood or to protect him against the ravages of insects and diseases, engineering studies on road building, irrigation, and drainage, economic studies relating to farm management, cost of production, etc., etc.

Taken together, these projects constitute the largest amount of definite and systematic investigation, agricultural or otherwise, conducted under a single organization anywhere in the world. United with the similar work of the state experiment stations, they are accumulating a body of knowledge relating to agriculture which already constitutes by far the largest contribution to the science of agriculture. In this way a broad, sure, and permanent foundation for the future agricultural prosperity of the United States is being laid.

As perhaps a natural outgrowth of its functions relating to the industry which is most fundamental to human life and civilization, the Department has taken on an increasing amount of work outside the field of agriculture. Such, for example, is a large part of the meteorological work of the Weather Bureau, the inspection of drugs, investigations on human nutrition, studies of household and disease-causing insects, biological investigations relating to human diseases, etc. Part of this has been given to the Department under a wise administrative policy which seeks to make the most effective use of existing governmental agencies and facilities, instead of creating new ones.

As a public agency for the dissemination of information on agricultural subjects the work of the Department has reached vast proportions. During the year ended June 30, 1912, it issued 2,110 publications, aggregating 34,678,557 copies. Many of these are technical reports of scientific investigations, published in small editions, but others are popular in character and are widely distributed. Over nine million copies of Farmers' Bulletins are sent out annually, and as they are distributed largely through Congressmen they go into all the rural districts. The "Yearbook," a bound volume of about seven hundred pages, has an edition of a half million copies.

For many years past three technical periodicals have been issued—the Monthly Weather Review, the Crop Reporter, and Experiment Station Record. These are given wide distribution in this country and to a considerable extent abroad. In addition, the Bulletin of the Mount Weather Observatory is issued in a periodical series, and the Library puts out a Monthly Bulletin.

Included in the special equipment of the Department are three farms, one at Arlington, Va., of about four hundred acres, for plant work; another of about fifty acres at Bethesda, Md., for use in the study of animal diseases; and a comparatively new farm at Beltsville, Md., of four hundred and seventy-five acres of land, for experiments in animal husbandry and dairying.

The Department's Library contains a collection of 122,000 books and pamphlets, chiefly on agriculture and related sciences, and as far as known is the largest agricultural library extant. Nearly two thou-

sand periodicals are received currently. Its books are lent to workers all over the country, loans being made the past year in thirty-nine different States and Territories, serving in this way as a national library of agriculture.

Such is the present magnitude of the national department which stands for agriculture and for the broader relations of human welfare. It is no local institution but is national in the broadest sense. Its constituency is ninety million people who profit by its manifold activities in a thousand ways, and its field is every State and the island possessions, through which its local offices and laboratories and over eleven thousand of its workers are scattered. It has no regard for sectional divisions or political affiliations. Nor does it work unto itself, for in these years of development the principle of cooperation between the Nation and the State has been permanently established.

The past sixteen years is a remarkable record of growth in resources and responsibilities and lines of endeavor, a growth in which the personnel has been multiplied more than five times and the revenues nearly seven times. This has been built upon a confidence born of accomplishment and a widening view of the functions of the Federal Government.

The history of the experiment station movement in the United States has often been told in these pages and in other publications. Dr. White, in his admirable paper, reviewed this history in the light of contemporary conditions of agriculture and of science, and gave a forecast of future development.

Starting with the establishment of the first experiment station in Connecticut in 1875, the growth of stations under state patronage was slow and their revenues comparatively small up to the time when the movement became national. These pioneer stations, however, demonstrated the usefulness of such institutions and prepared the public mind and the national legislature for the important step which culminated in the passage of the Hatch Act on March 2, 1887. They furnished a vision and an imagination which enabled a foreshadowing of the work to be done.

The inadequacy of the existing basis for agricultural instruction had been realized by the agricultural colleges for several years, as had been the inability of the colleges under their limited organization to develop that basis as it should be. A convention of representatives of the land-grant colleges, held in Washington in 1883, approved a plan for the establishment of a station at each of the colleges, and a subsequent convention in 1885 reaffirmed this approval. Several bills providing federal appropriation were presented in succeeding Congresses, and strongly pressed by the agricultural colleges and the then existing experiment stations, but it was not until

1887 that a bill introduced by Hon. William H. Hatch, of Missouri, was enacted by Congress and approved by President Cleveland. Thus came into existence, a quarter of a century ago, that great arm of the public service, the American agricultural experiment station, which in this relatively short period has given such an impetus to agricultural education and to a more intelligent agriculture, and been a national force for the instruction of the farmer.

The stations were regarded as state institutions from the beginning, and this subjected them to local conditions, pecuniary, political, and administrative, which for a time retarded their proper development in some instances. In the early period "it was inevitable that there should have been more or less of groping after stability and accurate consciousness of purpose. There was undoubtedly much effort that was unwise, much labor that was useless, much duplication that was unnecessary, much wastefulness of both energy and means."

Gradually, however, these conditions were remedied. Greater stability prevailed. The true mission of the station, the necessity for freedom from interference and large liberty in developing its methods and conducting its studies, were recognized and secured. As time passed and their potential capabilities were made manifest, the need developed for larger appropriations and for a more fundamental character of investigation. "In the first place, their resources were inadequate to their needs. States and communities had not yet been quickened to a sufficient supplementing of the initial federal grants. In the second place, the time had arrived when mere experimentation for the repeated corroboration of fairly well established truths should largely cease, and research and investigation for the acquiring of new and larger truths be more extensively prosecuted."

This resulted in the passage of an act introduced by Henry Cullen Adams, of Wisconsin, which was signed by President Roosevelt March 16, 1906. This new act doubled the federal appropriation to the stations in a period of five years, the federal appropriation reaching \$30,000 to each State in 1911, or a total of \$1,440,000 a year. Its terms were so drawn as to restrict the use of the new appropriation to the conduct of original investigation and research, as distinguished from the simpler experiments and trials which had been so much in demand. The standards set soon affected the work of the stations as a whole, resulting in a higher grade of product, and led to a sharper definition of their duties as distinguished from those of the teaching departments of the college and the manifold enterprises for extension teaching. The new provision called for more thoroughly trained men; and the differentiation of duties, with the larger freedom for concentration on research, attracted a class of workers who had heretofore looked askance at the experiment station as a field of activity.

Reviewing this new era, Dr. White said: "In the six years since the passage of the Adams Act the work and utility of the stations have enormously increased and expanded. Desultory and inconsequent experimentation has been largely discontinued; definiteness in experiment work has been more clearly established, and genuine scientific research along all the lines of the natural sciences related to agriculture have been begun. A large and able body of competent investigators has been developed, and the quality and value of their work challenges admiring comparison with the output of the laboratories of the world devoted to pure research in all the branches of biology, chemistry, and physics. Through the station publications and otherwise a body of new truth, demonstrated or suspected, has been given immediately to the workers in the fields for adoption, scrutiny, or test, and as a result it is probably true that in America scientific agriculture—and that means intelligent agriculture, economic agriculture—has made greater progress in the last ten years than in all the years which went before."

In the six years since the Adams Act passed, the revenues of the stations from federal and state sources have nearly doubled, amounting in the fiscal year 1912 to practically \$3,850,000, while the staff of officers and workers has increased nearly 85 per cent, the rolls at the close of 1912 numbering no less than 1,750 persons.

Dr. White outlined the modern conception of the experiment station as that of "a scientific laboratory in the fullest and purest sense, given over to varied but purely scientific work, with fields and barns and herds ranking with microscope, balance, and burette as mere implements of research. It is experimental only so far as it may test, on a strictly laboratory scale, the suggestions of research. It is the investigative department of the college to which it may be attached and, as such, may be called upon only to furnish new truths to be taught in the class room and the laboratory, in the extension lecture and on the demonstration farm. With this distinctive and restricted purpose the field of its operation is yet ample and sufficient. . . .

"The acquisition of knowledge must precede its application, and further real progress in agriculture must, therefore, come not so much from improved instruction in the schools, from increase in our extension teaching, or from demonstration in the field, valuable and important as these may be, but mainly from research in the station laboratory. . . .

"And yet a greater service may the station render to the State. Among all the public institutions, it should stand preeminently to illustrate the persistent, untiring search for truth. . . . For it is the search after truth that is the basis of moral training, and it is the possession of truth that, alone, shall make us free."

Throughout the last quarter century of development, the Department of Agriculture has been in close cooperation with the Association of American Agricultural Colleges and Experiment Stations and the institutions represented in it. There has also been a constant interchange between them. One secretary and three assistant secretaries have come from the agricultural colleges and experiment stations. Numerous subordinate officers, especially in the scientific service, have been drawn from these institutions, where they have received their special training. On the other hand, many Department officers have gone into the faculties of the agricultural colleges and the staffs of the experiment stations. Constantly increasing, and in the aggregate large, amounts of Department funds have been used in cooperation with the colleges and stations in a great variety of enterprises.

This is a natural and a happy condition, a recognition of the fact that problems and principles are broader than institutions or men, and that in their common effort for the advancement of agriculture through investigation and demonstration the facilities of the National Department and the state experiment stations supplement each other. Each has shared in the other's progress and achievements, and the success and influence of the one can rarely be adequately measured without recognition of the other.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

**Phytin and pyrophosphoric acid esters of inosit, II**, R. J. ANDERSON (*New York State Sta. Tech. Bul.* 21, pp. 3-16).—Continuing previous work (E. S. R., 27, p. 406), the author describes as new salts of phytic acid, calcium-magnesium-potassium phytate, penta-calcium phytate, tetra-calcium phytate, penta-magnesium phytate, the copper salts obtained when precipitating phytic acid with copper acetate, octa-silver phytate, and hepta-silver phytate. "Efforts to synthesize phytic acid by acting on dry inosit with dry pyrophosphoric acid lead to the formation of esters. Two of these, viz. the di-pyrophosphoric acid ester of inosit and a di-inosit tri-pyrophosphoric acid ester were obtained in pure form and analyzed. These esters are very similar to phytic acid in appearance, taste, and reactions. They yield similar acid salts and on hydrolysis inosit and phosphoric acid are produced."

The study was conducted in conjunction with an investigation in regard to the form in which phytin exists in wheat bran, and which will be reported upon later.

**Studies on enzym action.—I. Some experiments with the castor bean lipase**, K. G. FALK and J. M. NELSON (*Jour. Amer. Chem. Soc.*, 34 (1912), No. 5, pp. 735-745).—A comparative study was made of the hydrolysis of methyl acetate, ethyl butyrate, and olive oil caused by the castor bean lipase. Adding small amounts of alkali at the beginning of the action had no appreciable influence on the subsequent hydrolysis with methyl acetate, but with ethyl butyrate the action was different, depending upon the amounts of alkali added.

"In ether saturated with water, and acetone containing a small amount of water, as solvents, methyl acetate was hydrolyzed to a considerable extent with lipase both at the ordinary and at more elevated temperatures. Small amounts of an active constituent were extracted from the lipase preparation by water and by ethyl acetate. By the electrolysis in water of the lipase preparation, a substance was produced in the anode solution, probably by oxidation, showing marked hydrolytic action."

**Rôle of electrolytes in the action of ferments of animal origin**, H. BIERRY (*Biochem. Ztschr.*, 40 (1912), No. 5-6, pp. 357-369).—It was found that the pancreatic and gastric juices of dogs lost their starch-hydrolyzing property when subjected to dialysis with distilled water. The presence of chlorin or bromin ions was found to be absolutely essential to the activity of animal amylases. Vegetable amylase and lactase, and emulsin of animal origin, retain their cleaving power even when chlorids are absent.

**The hydrolytic action of hydrogen peroxid**, C. NEUBERG and S. MIURA (*Biochem. Ztschr.*, 36 (1911), No. 1, pp. 37-43).—The preparations used in this work were ovalbumin, gelatin, glycogen, various starches, inulin, nucleic acid from yeast, the sulphuric acid salt of chondroitin, and lecithin. Marked cleavage was noted at ordinary temperatures with all of these substances.

The ignition of precipitates without the use of the blast lamp, P. H. WALKER and J. B. WILSON (*U. S. Dept. Agr., Bur. Chem. Circ. 101, pp. 8*).—"An attempt has been made to determine whether alumina and silica can be ignited to constant weight without the use of a blast lamp, and as a result the authors are of the opinion that with slow initial ignition and final heating at the highest temperature that can be obtained with a burner, silica is practically always reduced to constant weight in 2 hours and generally in 1 hour. Alumina requires a somewhat longer period. About 3 hours reduces the weight to within the limit of error of the determination."

Precipitating agents for amino acids, C. NEUBERG and J. KERB (*Biochem. Ztschr., 40 (1912), No. 5-6, pp. 498-502*).—A universal precipitating agent for amino acids was found in a solution of mercuric acetate made alkaline with sodium carbonate. If to a solution of glycocoll, a saturated or a 10 per cent solution of sodium carbonate is added to alkalinity and then followed with a 25 per cent solution of mercuric acetate a white precipitate is obtained. By the judicious addition of the reagents in turn and then alcohol, a dense white precipitate is produced which is nearly quantitative. The process consists not only in obtaining the mercuric salt of the amino acid but also represents a complicated reaction in which the elements which constitute carbon dioxide come into play. Probably the basic salts of the corresponding carbamic acids are involved. The method does not possess the sharpness or definiteness of phosphotungstic acid with the diamino acids.

A delicate method for determining minute quantities of chlorophyll, C. A. JACOBSON (*Jour. Amer. Chem. Soc., 34 (1912), No. 9, pp. 1266-1269, pls. 4*).—A description is given of a method for determining the quantity of chlorophyll in leaves with a green weight less than 1 gm. This consists of a comparison of the intensity of the chlorophyll absorption bands of the solution to be examined with the intensity of the corresponding bands produced by solutions of known concentrations.

Colorimetric determination of phosphoric acid in arable soils, C. R. HERRERA (*An. Inst. Méd. Nac. [Mexico], 10 (1908), pp. 271-276; abs. in Chem. Abs., 6 (1912), No. 5, p. 662*).—The method is as follows:

"Twenty gm. soil, dried at 110°, are heated to low redness in a platinum crucible to destroy organic matter and digested with nitric acid on a water bath for 5 hours with frequent shaking. The filtered solution is evaporated to dryness in a platinum dish, the oxides of iron and aluminum dissolved in 5 cc. each of nitric acid and water, and filtered from silica. The temperature should be kept below 120° in order to prevent formation of alkali and alkaline earth silicates which would later form silicomolybdates. The filtrate is precipitated with ammonium molybdate, the precipitate dissolved in ammonia and, after addition of potassium ferrocyanid, compared with a standard solution prepared from pure acid sodium phosphate. Citrate-soluble phosphoric acid may be determined in a similar manner."

Determination of moisture in cereals and cereal products, A. FORNET (*Ztschr. Gesam. Getreidew., 3 (1911), Nos. 4, pp. 92-98; 5, pp. 113-118; 4 (1912), No. 3, pp. 73-77, figs. 3*).—This is a study of methods. It considers the various temperatures and apparatus proposed for determining the moisture in cereals and cereal products, and also points out their disadvantages, particularly the Duvel (*E. S. R., 18, p. 1122*) and Hoffmann apparatus.

The author also describes a rapid drying apparatus, which utilizes a current of air and a temperature of 160° C. He finds that working under these conditions the apparatus will furnish results in from 7 to 14 minutes, depending upon the material under examination, which are practically identical with

those obtained by drying at 105° for 15 hours or so. A scale devised by the author for rapid weighing is also illustrated and described.

The determination of sugar in natural substances, C. NEUBERG and M. ISHIDA (*Biochem. Ztschr.*, 37 (1911), No. 1-2, pp. 142-169; *abs. in Zentbl. Physiol.*, 25 (1911), No. 25, pp. 1199, 1200).—The polarimetric determination of sugar in all cases is connected with a certain amount of error where optically active substances (cleavage products), such as peptone, amido acids, amins, etc., are present, as they are as a rule in human foodstuffs, but if the solution containing them is first treated with mercuric acetate and then with phosphotungstic acid interfering substances will be removed. The author first adds a 50 per cent solution in water of mercuric acetate until no more precipitation takes place, filters off the sediment, and then adds a 25 per cent aqueous solution of phosphotungstic acid until no more precipitation occurs. Care must be taken not to add a large excess of mercuric acetate. No sugar is retained in the precipitate, and that in the filtered fluid may be determined by either the reduction or the polarimetric method.

In regard to the composition of Fehling's solution as used at the present time, O. LÜNING (*Chem. Ztg.*, 36 (1912), No. 14, p. 121).—Attention is drawn to certain inaccuracies in several of the published directions for preparing Fehling's solution.

The amount of formic acid in honey, H. FINCKE (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 23 (1912), No. 6, pp. 255-267; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 8, p. 402).—Continuing previous work (E. S. R., 26, p. 312), honey was not always found to contain formic acid, but most of that examined contained a volatile acid which reduced mercuric chlorid in amounts varying from 0.003 to 0.02 per cent when calculated as formic acid. This acid was present in both the free and combined state. Esters of formic acid could not be detected.

Attention is called to the fact that small quantities of formic acid are obtained if invert sugar is distilled with steam, the quantity depending upon the acidity of the solution. Sucrose when inverted with invertase does not yield formic acid on distillation. Honeys free from formic acid were not found to yield any more volatile acids than those derived from a corresponding amount of invert sugar.

The analysis of vinegar, J. H. PATERSON (*Proc. Univ. Durham Phil. Soc.*, 4 (1911-12), No. 3, pp. 144-146).—Normal vinegar contains acetic acid, and small quantities of sodium tartrate and acetate. If the acetic acid is titrated with a standard alkali solution, and the solution then titrated back with a standard acid solution, using methyl orange as an indicator, the amount of acid will be, therefore, a little in excess of that which would be equivalent to the free acid found by the alkali titration. Vinegar adulterated with mineral acid will not contain tartrates and acetates, but free acetic and tartaric acids will be present.

The method used is as follows: "A sample of the vinegar is boiled under a reflux condenser with about  $\frac{1}{2}$  of its weight of animal charcoal (the charcoal is previously treated with dilute hydrochloric acid to remove all carbonates, well washed, and dried for some time at 110° C.). The liquid is then filtered and the interior of the condenser washed into the filtrate with some of the filtered liquor. About 20 gm. of the filtrate are then weighed out and diluted to 100 cc. with distilled water. Portions of 25 cc. are carefully titrated with tenth-normal caustic potash, using phenolphthalein as indicator. The solution thus obtained is diluted to a known volume (about 100 cc.), and 6 drops of methyl orange added. Decinormal sulphuric acid is then run in until a pink color without any yellow shade is produced."

A blank of distilled water is then titrated in the same way, and the true volume of acid required for the back-titration of the sodium acetate obtained by difference. Solutions containing known amounts of acetic acid, sodium acetate, and sulphuric acid were analyzed by this method.

**Analysis of paprika**, A. DE SIGMOND and M. VUK (*Kisérlet. Közlem.*, 14 (1911), No. 5, pp. 757-792).—The determination of the iodine number and the refraction of the ether extract will not detect adulterations of paprika with foreign oils. The standards of the United States require that paprika represent only the dried fruit of *Capsicum annuum*, while in Hungary the seeds are not excluded. As the seeds contain more oil, the United States standard of 15 per cent is exceeded.

Air-dried paprika contains more or less moisture, so that the results obtained should be compared on a dry basis. The results obtained by drying in a current of air differ markedly from those after drying in a current of illuminating gas. It is stated that Hungarian paprika can not be distinguished from foreign paprikas on the basis of a chemical examination.

**Contribution to the detection of benzoic acid in foods and condiments**, E. POLENSKE (*Arb. K. Gsndhtsamtl.*, 38 (1911), No. 2, pp. 149-154).—The author has elaborated a method for determining the total benzoic acid in red bilberries and in bilberry compote, and presents a method for the isolation and qualitative detection of benzoic acid in food products.

**Determination of the total solids in milk**, A. SPLITTGERBER (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 22 (1911), No. 10, pp. 583-599; *abs. in Chem. Zentbl.*, 1912, I, No. 5, pp. 377, 378; *Jour. Soc. Chem. Indus.*, 31 (1912), No. 1, pp. 40, 41).—What is deemed the most appropriate method for determining the total solids in milk consists in drying from 3 to 4 gm. of milk in a flat-bottomed dish with or without the addition of acetone or alcohol. The method yields results with normal, rich, skim, and watered milk, which compare well with the figures obtained by Fleischmann's formula. The ordinary water oven requires 1 hour for the process, while the Soxhlet oven needs only 30 minutes when a watery solution of glycerin (55 per cent) is used. The addition of 3 drops of acetic acid or formaldehyde to the milk before evaporation yields results which are too high. Old milks yield low results. "If the milk contains calcium succrate or sodium carbonate, the quantity of total solids found by direct determination is unreliable, but in such cases the calculated figure may be relied on as trustworthy."

**The chlorin content of milk**, P. POETSCHKE (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 1, pp. 38-40).—The chlorin determinations recorded were made by the author's method, which consists in removal of the fat and proteids with copper sulphate and sodium hydroxid. The filtrate is acidified with nitric acid and titrated by Volhard's method. Total solids were determined with the aid of a special pipette (E. S. R., 26, p. 806) devised to deliver 5 gm. of milk.

The average amount of chlorin found, expressed as sodium chlorid, was 0.17 per cent, and ranged from 0.112 to 0.335 per cent. The average ratio of sodium chlorid to ash was 1:4.5.

Titrating the milk directly for its chlorin content, as recommended by Richmond, gave erroneous results. Formaldehyde present to the extent of 1:500 in milk did not influence the results obtained with the author's method.

**A rapid means for determining the fat in milk according to the Röse-Gottlieb method**, E. RUPP and A. MÜLLER (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 23 (1912), No. 7, pp. 338, 339).—The author found that the separation of the ether can be accelerated by adding gum tragacanth to the mixture and shaking.

The detection of coconut fat in butter and lard, E. POLENSKE (*Arb. K. Gsndhtsamtl.*, 38 (1911), No. 3, pp. 402-414).—It appears that the method of Ewers (*E. S. R.*, 23, p. 417) and Fendler (*E. S. R.*, 23, p. 418) can not be used for this purpose. The Polenske method, on the other hand, will give trustworthy results. The results of examining 34 fresh and 8 old butters are given in detail.

Determination of fat in feeds by extracting in the cold, C. GRIMME (*Chem. Rev. Fett u. Harz Indus.*, 19 (1912), No. 1, pp. 1-5).—As considerable danger from fire exists when using ether for extracting fats, tests were conducted with chloroform, carbon tetrachlorid, and di-, tri-, and per-chlorethylene, for determining their value as fat solvents for air-dry cotton-seed meal.

Carbon tetrachlorid and tri-chlorethylene were the only reagents which gave results comparing well with those obtained with ether. The method finally adopted was as follows: Ten gm. of the air-dry sample is shaken with 100 cc. of either carbon tetrachlorid or tri-chlorethylene for  $\frac{3}{4}$  hour in a 150 cc. flask in the cold and with the aid of the shaking machine. After allowing the insoluble particles to settle for 30 minutes, 50 cc. of the filtered fat solution is freed from the solvent by distillation and then dried for about 1 hour (by occasionally blowing air over it) at a temperature of 105° C. Multiplying by 20 the figures obtained gives the percentage of fat in the feed, providing the material did not contain more than 10 per cent of fat. If more fat is present corrections should be applied, viz. for 15 per cent fat +0.2 per cent, and for 20 per cent fat +0.4 per cent. The method gave good results with cotton-seed meal, peanut cake, peanut meal, rape cake, sunflower cake, coconut cake, soy-bean meal, linseed meal, bran, rice-feed meal, fish meal, corn meal, wheat germs, and rye bran.

Grading rosin at the still, F. P. VEITCH and C. F. SAMMET (*U. S. Dept. Agr., Bur. Chem. Circ.* 100, pp. 4, fig. 1.)—A method is proposed whereby a producer can grade rosin at the still when it is made and which does away with the cutting of rosin samples. The method consists of pouring the liquefied rosin with an ordinary tin dipper into a mold made of ordinary roofing tin. When cool the samples can be compared with a set of standard types of rosin.

“By far too much low-grade rosin is being made. There are three chief causes for this: First, the presence in the gum in the still of considerable quantities of wood, bark, pine needles, charcoal, and dirt which, through carelessness, accident, or both, have gotten into the gum in the woods and the larger part of which remains in the still during distillation. . . . Second, excessive heating or prolonged heating of the rosin in the still at the close of distillation, largely for the purpose of removing all turpentine and water which it may contain. Third, the presence in the finished rosin of much finely divided foreign material, such as charcoal and earth mentioned above, due to faulty straining of the finished rosin. . . . Rosins which had been graded A, B, C, D, and E, when dissolved in turpentine or alcohol, carefully strained, and the solvent evaporated with heat, all grade higher, many of them F or better, thus showing that these rosins were graded low because of the foreign material they contained, which had not been removed in straining, rather than because of the color of the rosin itself.”

Oil from plants belonging to the order Papilionaceæ, C. GRIMME (*Pharm. Zentralhalle*, 52 (1911), No. 43, pp. 1141-1149; *abs. in Chem. Zentbl.*, 1911, II, No. 23, pp. 1739, 1740; *Jour. Soc. Chem. Indus.*, 30 (1911), No. 24, p. 1460).—The following seeds were examined for their oil content: *Cicer arietinum*, *Pisum sativum*, *Vicia faba*, *V. sativa*, *V. sepium*, *Lens esculenta*, *Cajanus*

*indicus*, *Phaseolus mungo*, *P. vulgaris albus*, *P. coccineus*, *P. lunatus*, *P. inamœnus*, *Dolichos lablab*, *Vigna catjang*, *Canavalia ensiformis*, and *Voandzeia subterranea*. Physical and chemical constants are reported, and the fatty acids were also studied. All the oils were nondrying in character.

**Heat of combustion of bagasse from Hawaiian cane**, R. S. NORRIS (*Hawaiian Sugar Planters' Sta., Agr. and Chem. Bul.* 40, pp. 5-23).—Using an At-water modification of the Berthelot bomb, the thermal value of fiber from leading varieties of Hawaiian cane was determined, primarily for the purpose of ascertaining whether the variation in the amount of steam obtained in factories when different kinds of cane are being ground is due to the thermal value of the bagasse used for firing.

"The results are practically the same as those obtained for the thermal value of cane fiber in other countries as [summarized] and show conclusively that the variation in the steam when different kinds of cane are being ground is not due to differences in the thermal value of the bagasse. The maximum thermal value found was 4,636 calories (8,334 B. T. U.) and the minimum 4,494 calories (8,089 B. T. U.)—a difference of only 3 per cent."

The 2 standard varieties of cane grown on the islands, Lahaina and Caledonia, were found to have high thermal values. The average thermal value of cane fiber grown at the station and on Hawaiian plantations was 4,600 calories, which is 100 calories more per kilogram than for the bagasse therefrom.

The carbon and hydrogen contents, respectively, were for the bagasse 48.13 and 5.63 per cent; for the fiber 48.9 and 6 per cent; for the rind fiber 48.75 and 5.85 per cent; and for the pith fiber 47.2 and 5.9 per cent. "The rind fiber was about 4 per cent higher in thermal value than the pith fiber. This would tend toward giving canes with stalks of small diameter a higher value than those with large stalks, but an examination of the results shows that this influence is overcome by other variations in the cane." The thermal value of fiber from nodes was found to be  $1\frac{1}{2}$  per cent higher than that from the internodes in the 2 standard varieties of cane in Hawaii.

On the basis of the values recorded the fuel values of various bagasses may be compared with one another, and bagasse with other fuels. Some figures for the thermal value of subsidiary fuels in cane sugar factories are also included.

A bibliography on bagasse as fuel is appended.

**Sisal and the utilization of sisal waste**, E. V. WILCOX and W. McGEORGE (*Hawaii Sta. Press Bul.* 35, pp. 24).—Continuing previous work (E. S. R., 15, p. 244), the conditions of the sisal industry in Hawaii were reviewed, and a chemical study of sisal and henequen was made for the purpose of finding a means of utilizing the residue after decortication as a fertilizer, stock food, or as a source of industrial alcohol.

The nitrogen content of 6 samples of waste was found to vary between 0.45 and 1.35 per cent; potash from 0.69 to 6.38 per cent; phosphoric acid from 0.46 to 2.79 per cent. Ash analyses of the leaves showed that "the plant feeds most heavily upon phosphates, lime, magnesia, potash, and soda, and since nearly all this mineral matter remains in the waste the analyses strongly indicate the advisability of returning the waste to the soil as fertilizer."

To use it as a stock food also seems possible, although it is first necessary to bring it to a dry condition. Converted into an air-dry form the minimum figures obtained were moisture 5 per cent, protein 5.78 per cent, nitrogen-free extract 60.01 per cent, fiber 17.97 per cent, and ash 11.24 per cent.

The chemical composition of the sisal leaf was as follows:

*Chemical composition of sisal leaves, calculated on a dry basis.*

Constituent.	Sample numbers.					
	1	2	3	4	5	6
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>

The sugars soluble in cold water were in every instance found to be apparently insoluble in alcohol. The sum of the water and alcohol-soluble substances were a fairly constant quantity in most cases. When the sugar content of fresh sisal leaves was high the percentage of gum was low. After such leaves were left in the laboratory for a month a considerable reduction of the total sugar content (from 36 to 12.14 per cent) and an increase in the gum content (from 15.67 to 39.53 per cent) took place.

The acid present in sisal was found to be lactic and the authors were not able to obtain a test for oxalic acid after boiling the leaves vigorously in water, but a faint test was obtained after boiling in a hydrochloric acid solution. Short leaves were found to possess a higher percentage of acid than longer ones.

"The sugar content of the fresh leaf varied from 2 to 7 per cent, making an average of 4.5 per cent, which theoretically would yield about 26 liters (or 6.5 gallons) absolute alcohol per ton of leaves. It is hardly conceivable that with such a sugar content this could be made a remunerative industry with the waste at hand."

Report in regard to the activities of the Pommritz Agricultural-Chemical Experiment Station, 1911, LOGES (*Ber. Agr. Chem. Vers. Stat. Pommritz, 1911, pp. 8*).—This is the report of the activities of this station for the year 1911, including among other data analyses of dairy products, fertilizers, feeding stuffs, and miscellaneous materials.

International catalogue of scientific literature, D—Chemistry (*Internat. Cat. Sci. Lit., 9 (1912), pp. VII+960*).—The literature indexed in this publication (*E. S. R., 24, p. 408*) is mainly that published in the year 1909, but includes some articles from 1901 to 1908 which were received too late for insertion in previous volumes, and also some entries dated 1910.

### METEOROLOGY—WATER.

The correlation between sunspots and the weather, A. GOCKEL (*Sci. Amer. Sup., 74 (1912), No. 1911, pp. 102, 103*).—The scientific evidence bearing on such correlation is reviewed. The correlation between sunspots and rain and between sunspots and terrestrial magnetism is considered to be established. It is also stated that the frequency of cyclones increases with the number of sunspots.

[Weather observations], M. A. BLAKE, B. D. HALSTED ET AL. (*New Jersey Stat. Rpt. 1910, pp. 81-86, 272-276*).—Observations on temperature, precipita-

tion, and evaporation at New Brunswick during 1910 and previous years are reported and briefly discussed.

**Weather report,** W. H. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 37 (1911), pp. 58-63).—Tabular summaries are given of observations on temperature, precipitation, and length of the growing season at representative stations in Ontario during 1911. There is also a record of wind movement during the year at Guelph.

**Swedish meteorological observations, 1911,** H. E. HAMBERG (*Mét. Iakttag. Sverige (Observ. Mét. Suéd.) K. Svenska Vetensk. Akad.*, 53 (1911), pp. X+157).—These are the usual meteorological summaries of observations made under the direction of the Central Meteorological Institute of Sweden.

**Duration of sunshine and insolation at Stockholm and Häfringe,** J. WESTMAN (*K. Svenska Vetensk. Akad. Handl.*, 47 (1911), No. 8, pp. 38; *abs. in Mét. Ztschr.*, 29 (1912), No. 10, pp. 489, 499).—Monthly and yearly sums of sunshine, total radiation, and vertical components of total radiation are given for Stockholm during 1907 to 1910 and for Häfringe for 1910.

**Frosts in New York,** W. M. WILSON (*New York Cornell Sta. Bul.* 316, pp. 505-513, *figs.* 18).—Conditions favoring the formation of frost and methods of protection which have been used with success are described with special reference to conditions prevailing in New York.

**Electric Niagaras and recent storms,** A. LAFOREST (*Jour. Soc. Nat. Hort. France*, 4. ser., 13 (1912), *Sept.*, pp. 572-574).—Several instances are cited in which the Eiffel Tower, acting as a so-called electric Niagara, had no influence in dissipating hail storms.

**Well water,** R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 37 (1911), pp. 71-73).—Sanitary analyses of 34 samples of well water from different parts of Ontario are reported. A large proportion of the samples showed evidence of contamination.

## SOILS—FERTILIZERS.

**The soils of Oregon,** C. E. BRADLEY (*Oregon Sta. Bul.* 112, pp. 48).—This bulletin reports the results of several years' work on the soils of Oregon and includes chemical analyses of a number of soil types from different parts of the State arranged by counties, and analyses of drainage waters from tanks under different cropping systems and fertilizers. Analyses of samples of water from the Columbia and the Willamette rivers are also reported.

"The soils grade from the rich black loams of the coastal plains and lower river courses of western Oregon to the extremely sandy soils of the eastern and the coarse granitic soils of the southern portion of the State, with many intermediate types. Volcanic rocks predominate in the northwest, and Oregon soils are largely derived from weathered basalt, diabase, and diorite, particularly in the eastern and western part of the State. In southern Oregon granites, limestones, and other metamorphic rock exist also and have, therefore, determined in part the mineral character of the soils of this section. Where the weathering process has taken place under humid conditions, as in western Oregon, clay loams rich in humus have been formed, while under the climatic influences of the arid or semiarid conditions of that portion of the State east of the Cascade range, a sandy soil has resulted."

It was found that there was little loss of the mineral elements by leaching, except in one case where considerable phosphoric acid was lost. Nitrogen was lost in appreciable quantities, particularly under summer fallow. This nitrogen loss was appreciably reduced by legume rotations.

It was found that, although the percentage of nitrogen remained practically constant under continued cropping for, in extreme cases, 25 years, there was a marked decrease in the carbon content.

"The loss of humus from these soils under the wheat-fallow system is a matter of serious import, and it would seem that methods for conserving this organic matter must be adopted if these soils are to maintain their productive-ness."

**Sandy soils of western and northern Michigan, J. A. JEFFERY** (*Michigan Sta. Circ. 16, pp. 101-105*).—These soils range from the coarser dune sands, which possess little or no agricultural value, to the finer Miami sands.

"The Miami sands vary from soils that possess much intrinsic agricultural value to soils that can never be made profitably productive under ordinary methods of management." The possible cropping value is indicated by the original vegetation which the soils are supporting or have supported. Potatoes, clover, rye, buckwheat, and in some cases wheat, oats, and barley are the crops best suited to the soils. "Truck crops do well, corn and beans do fairly well. Alfalfa promises to prove a very valuable crop for these soils. They are not adapted to the growing of sugar beets."

**Results of chemical studies of the cane soils of Java, T. MARR** (*Arch. Suikerindus. Nederland. Indië, 20 (1912), No. 32, pp. 1251-1314, pls. 11, fig. 1; Meded. Proefstat. Java-Suikerindus., 1912, No. 23, pp. 653-714, pls. 11, fig. 1*).—This is a compilation of physical and chemical analyses, made by different investigators during the last 25 years, of a large number of samples of cane soils from various districts of Java. See also a note by Mohr (*E. S. R., 25, p. 512*). The report includes a discussion of the topographical features of the various districts, the character and distribution of the soil types, and the amount of plant-food constituents of the soils.

**Soil mapping and geological-agronomic maps, W. KOEHNE** (*Landw. Hefte, 1912, No. 5, pp. 32*).—This is a general discussion of the scope and purpose of geological-agronomic soil maps, with particular reference to their practical value and interpretation by the farmer.

**The Mangum terrace in its relation to efficient farm management, J. S. GATES** (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 94, pp. 11, figs. 9*).—The advantages and construction of the Mangum terrace worked out by P. H. Mangum of Wake Forest, N. C., are briefly described. It is a broad bank of earth contouring the field at a grade of approximately 1½ in. to 14 ft. Under ordinary farm conditions, the most practical way of constructing the terrace is by back furrowing along the grade line.

The advantages of this system are stated to be its adaptation to all types of soil, especially to moderately rolling lands, the possibility of using extensive cultivation machinery and cultivating across the terrace, the saving of labor and land, and the ease of preserving the terrace when once constructed.

**Bacteriological studies of field soils.—I, The effects of lime, P. E. BROWN** (*Iowa Sta. Research Bul. 5, pp. 189-210*).—Previous experiments (*E. S. R., 26, p. 428*) having dealt with the effects of ground limestone on certain groups of soil bacteria under greenhouse conditions, similar experiments were conducted under field conditions. The results of the work in general were similar to those already noted.

**Bacteriological studies of field soils.—I, The effects of liming, P. E. BROWN** (*Centbl. Bakt. [etc.], 2. Abt., 35 (1912), No. 11-13, pp. 234-248*).—This is an abridged account of investigations noted above.

**Bacterial activities in frozen soils, P. E. BROWN and R. E. SMITH** (*Iowa Sta. Research Bul. 4, pp. 157-184; Centbl. Bakt. [etc.], 2. Abt., 34 (1912), No. 14-17,*

pp. 369-385).—This is a detailed account of investigations which have already been noted from a briefer paper (E. S. R., 26, p. 816).

**Relations of the plant to the nutritive elements of the soil: The law of minimum and the law of physiological ratios, P. MAZÉ** (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 25, pp. 1711-1717, fig. 1; *abs. in Rev. Gén. Agron., n. ser.*, 7 (1912), No. 8, pp. 292-295; *Jour. Soc. Chem. Indus.*, 31 (1912), No. 14, p. 695).—The author's experiments with maize and *Aspergillus niger*, using various kinds, amounts, and relative proportions of mineral substances in the culture solutions, led to the conclusion that the law of minimum, particularly as defined by Mitscherlich (E. S. R., 25, p. 825) is a purely speculative conception. The relation of the plant to its nutritive substratum is determined by complex conditions controlled by a law which is designated the law of physiological ratios, that is, the growth of the plant is determined not solely by the nutritive constituent present in minimum amount but by the concentration and relative proportions of the constituents in the nutritive medium.

**The law of minimum, E. A. MITSCHERLICH, T. PFEIFFER, and O. FRÖHLICH** (*Landw. Vers. Stat.*, 77 (1912), No. 5-6, pp. 413-439, figs. 4).—This is a series of three controversial articles on this subject. See above.

**Experiments on ammonia and nitrate formation in soils, J. G. LIPMAN, P. E. BROWN, and I. L. OWEN** (*New Jersey Stas. Rpt.*, 1910, pp. 89-124).—In continuation of previous investigations (E. S. R., 25, p. 423) experiments were made to test further the accuracy of the method used and "to accumulate data on the decomposition of protein compounds in the soil." The experiments here reported dealt with the effect of mechanical composition of the soil, moisture conditions, lime, and various physical and chemical factors on the formation of ammonia in soils. The results obtained in a series of experiments uniformly indicated a high degree of accuracy for the method.

Varying the proportion of sand in the soil had little effect on the formation of ammonia from dried blood, but affected to a marked degree ammonia accumulation, the latter declining as the proportion of sand increased. In pot experiments it was found that addition of sand to soil increased the availability of nitrogen as measured by the nitrogen content of the crop.

"The influence of the increasing amounts of moisture in the soil is apparent, on the one hand, in the increasing yields of dry matter and, on the other, in the decreasing proportion of nitrogen in the latter. The average yield of dry matter gradually rose from 13 gm. to 20.75 gm., but when the proportion of water in the soil mixture was increased from 13 to 15 per cent the yield of dry matter was somewhat decreased. The proportion of nitrogen in the dry matter was highest when the soil mixture contained only 5 per cent of moisture. It was least when the soil mixture contained 15 per cent of moisture. Similarly, the yields of total nitrogen increased from 266.86 to 292.47 mg. when the moisture content in the soil rose from 7 to 9 per cent. Further additions of moisture were followed by corresponding increases, the maximum yield being attained in the soil mixtures containing 13 per cent of water. After that there was a small reduction in the yield of nitrogen."

"The decomposition of organic matter in the soil was favored or retarded by additions of magnesian and nonmagnesian lime according to the character of the organic matter." In experiments with a commercial carbonate of lime containing 2 per cent of boron the latter proved injurious to higher plants and to decay bacteria in the soil.

Wide variations were found in the ammonia formation in soils from different sources.

The addition of monocalcic and dicalcic phosphates to soil greatly increased ammonia formation. Tricalcic phosphate was without effect. "It seems, there-

fore, that the monocalcic and dicalcic phosphate were equally effective in stimulating the activities of the decay bacteria."

It was found "that with a proper supply of lime peat may become a very satisfactory medium for the development of ammonifying bacteria."

The influence of an addition of sugar on the productivity of soils, T. PFEIFFER and E. BLANCK (*Mitt. Landw. Inst. Breslau, 6 (1912), No. 4, pp. 601-612, fig. 1*).—The authors briefly review the work on this subject by A. Koch, Lemmermann et al., and Schneidewind et al. (*E. S. R., 20, p. 17; 24, p. 327; 26, p. 319*), and report a continuation of studies (*E. S. R., 24, p. 319*) of the effect of sugar with and without phosphoric acid on the nitrogen supply of different soil plats, as measured by yield of oats and turnips, using 1 kg. of sugar and 100 gm. of Thomas meal per square meter.

The results showed a slightly injurious effect of the sugar on the yield of the oat crop. The after effects of the sugar on the turnips were apparently slightly beneficial. It is believed, therefore, that the importance of the fertilizing effect of sugar or organic substances has been overrated. Further studies with sugar in combination with potash and phosphatic fertilizers are being made.

On the action of an addition of alumina gel to the soil on the assimilation of phosphoric acid by the plants, T. PFEIFFER and E. BLANCK (*Mitt. Landw. Inst. Breslau, 6 (1912), No. 4, pp. 613-617*).—This is a continuation of previous work (*E. S. R., 25, p. 121*), and reports studies of the effect of alumina on the assimilation of phosphoric acid by yellow lupines, using 390 gm. of aluminum hydroxid, containing 2.1 per cent  $Al_2O_3$ , per 18 kg. of sand in pots fertilized with potassium phosphate.

The results, in general, confirmed those of the previous experiments and indicated that the phosphoric acid did not go into absorptive but into chemical combination.

Brief reference is also made to a study of the lime intolerance of lupines. It was found that the iron content was lower for plants grown on a soil rich in calcium carbonate. The potash content of the plants was not reduced by addition of lime to the soil.

The effect of heating and antiseptic treatment on the solubility of fertilizing ingredients in soils, H. I. JENSEN (*Jour. and Proc. Roy. Soc. N. S. Wales, 45 (1911), pt. 2, pp. 169-175*).—Previous investigations bearing on this subject by Russell and Hutchinson (*E. S. R., 22, p. 121*), Pickering (*E. S. R., 24, p. 420*), Fraps (*E. S. R., 26, p. 726*), and Greig-Smith (*E. S. R., 25, p. 214*) are briefly referred to, and studies of the solubility in strong hydrochloric acid, 1 per cent citric acid, and fifth-normal nitric acid of the fertilizing constituents in 6 soils untreated and (presumably) sterilized by heat are reported.

The results obtained indicate that the treatment (?) made no appreciable difference in the solubility of the mineral fertilizing ingredients in acids and fail to support Greig-Smith's theory of waterproofing the soil particles by agricere. "The evidence is therefore decidedly in favor of the view taken by Russell and Hutchison, that the increased fertility is due to the destruction of the protozoa and nitric acid-producing bacteria and a quick revival of the ammonia-forming bacterial flora."

Influence of the micro-organisms carried to the soil by night soil on the fertilizing effect of the same, G. MASONI (*Staz. Sper. Agr. Ital., 45 (1912), No. 3, pp. 191-223; abs. in Chem. Zentbl., 1912, I, No. 20, p. 1635*).—In pot tests with unmanured soil, that receiving untreated night soil, and that receiving night soil sterilized by heat, sulphuric acid (1 per cent), and sodium sulphate (equivalent to 1 per cent sulphuric acid), the yields were as a rule greater

with sterilized than with untreated night soil on both normal and sterilized soil.

**Report of Leteensuo Moor Experiment Station, 1912.** E. F. SIMOLA (*Finska Mosskulturför. Årsbok, 16 (1912), No. 1, pp. 92-116, figs. 9*).—A description is given of the station and its equipment, and brief mention is made of the fertilizer trials and other experiments in progress.

**Report of the South Oesterbotten Moor Experiment Station, 1912.** A. E. RAUTAKOSKI (*Finska Mosskulturför. Årsbok, 16 (1912), No. 1, pp. 117-117, figs. 10*).—A report similar to that of the Leteensuo Moor Experiment Station referred to above.

**The nitrate of soda industry of Chile.** B. D. OSSA (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 2 (1912), Sect. II, pp. 187-204, figs. 10*).—This article contains substantially the same information given in a previous article which has already been noted (E. S. R., 24, p. 526).

The author concludes that the Chilean nitrate deposits are capable of furnishing all of the nitrogen required by the world for a century. The technique of the industry is being developed and improved so that the price of nitrogen in nitrate of soda can be still further reduced.

**The use of nitrate of soda in commercial fertilizers.** C. S. CATHCART (*New Jersey Stas. Rpt. 1910, pp. 41-48*).—The essential features of this article have been noted from another source (E. S. R., 25, p. 120).

**The availability of nitrogenous materials as measured by ammonification.** J. G. LIPMAN, P. E. BROWN, and I. L. OWEN (*New Jersey Stas. Rpt. 1910, pp. 127-182*).—The availability of nitrogen in dried blood, tankage, ground fish, corn meal, rice, wheat, and rye flours, cotton-seed meal, linseed meal, cowpea meal, and soy-bean meal was measured by vegetation experiments and determined by ammonia formation under different conditions by the following method:

"A large quantity of air-dry, silt loam was sifted and thoroughly mixed so as to furnish a uniform medium for bacterial growth. One hundred gm. quantities of this soil were placed in tumblers, the nitrogenous material was added and carefully mixed with the soil, and the latter was then moistened with a quantity of water or fresh soil infusion, sufficient to establish optimum moisture conditions. The tumblers were covered with Petri dish covers and kept in the incubator at 27° C. for a definite period. Subsequently the different soil portions were transferred to copper flasks, about 200 cc. of water and magnesia were added, and the ammonia was distilled off and titrated against standard hydrochloric acid."

The availability of the nitrogen of the vegetable substances was also determined by their rate of nitrification. In general the results of the nitrification experiments were in agreement with those of the ammonification experiments. "Both methods distinguished between available and unavailable nitrogen compounds in so far as the micro-organisms as well as the higher plants are concerned. They possess, therefore, a direct value for both experimental and control work."

In experiments with combinations of peat and dried blood it was found that "the nitrogen compounds in the peat were so inert as to be scarcely affected in their decomposition by the presence of readily assimilable nitrogen compounds. On the other hand, the latter were unfavorably affected by the peat, for they furnished less nitrogen to the plants when the peat was mixed with them."

The method was found to be applicable to the determination of the availability of nitrogen in mixed substances and complete fertilizers.

**Experiments with new nitrogenous fertilizers, 1908-1911, S. RHODIN** (*K. Landtbr. Akad. Handl. och Tidskr.*, 51 (1912), No. 5, pp. 362-382).—These experiments were a continuation of an investigation by the author commenced in 1903 (*E. S. R.*, 19, p. 220). The effects of fertilization with Norwegian nitrate, sodium nitrate, ammonium sulphate, and cyanamid in connection with other fertilizers were compared on small grains, grass land, potatoes, and mangels.

It was found, as the average for all trials conducted, that the fertilizing effect of cyanamid measured by the increase in the value of the crops raised was from 68 to 70 per cent of that of sodium nitrate and similar to ammonium sulphate, that of Norwegian nitrate being 96 per cent. The experiments, in general, point to the value of cyanamid for the Swedish farmer. While many questions relating to its effects and best methods of application still have to be studied, the results obtained suggest that this fertilizer may prove of great economic value to Sweden as it will tend to make the farmer independent of imported nitrogenous fertilizers.

**Destruction of wild mustard by means of lime nitrogen, H. LIPSCHÜTZ** (*Deut. Landw. Presse*, 39 (1912), No. 68, p. 784, figs. 3).—To oats, which had been seeded on March 27 and which contained a large admixture of wild mustard, lime nitrogen was applied about the end of April at the rate of about 160 lbs. per acre in the early morning when the dew was on. This application produced some temporary injury to the oats, which was soon overcome, but almost completely destroyed the wild mustard.

**Seaweed, potash, and iodine: A criticism, H. KNUDSEN** (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 8, pp. 623, 624).—This is a criticism of certain conclusions by Cameron (*E. S. R.*, 27, p. 22) regarding the value of Pacific coast seaweed as a source of potash. It is maintained that "a potash industry on the basis of seaweed will first and last depend on the content of iodine in the marine plants," and that "as yet we possess very little of value and very little authentic information to solve the question: 'Is it possible to build up a lucrative industry on the abundant growth of seaweed at the Pacific coast?'"

**The extraction of potash and alumina from feldspar, H. W. FOOTE and S. R. SCHOLES** (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 5, p. 377; *Chem. News*, 106 (1912), No. 2753, p. 106).—Experiments are reported which show that almost complete decomposition of feldspar can be secured by heating it to a temperature well above 100° C. under pressure with hydrofluoric acid, which seems to act in this case as a catalytic agent.

**The production of available potash from the natural silicates, A. S. CUSHMAN and G. W. COGGESHALL** (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York]*, 5 (1912), Sect. IIIc, pp. 33-49; *Jour. Indus. and Engin. Chem.*, 4 (1912), No. 11, pp. 821-827).—The various processes which have been proposed for this purpose are reviewed, particular attention being given to a process devised by the authors in which lime and salt or calcium chloride are used as the reducing agents in a new rotary kiln.

This process "depends upon a previous treatment before furnacing, consisting of a method of aggregating or clumping the mix so that chemical contact of the reacting substances is brought about during the subsequent processing. The qualitative and quantitative results obtained on a number of experimental trials on a mill scale of operation are presented and discussed. It is shown that it is possible to economically manufacture a potash fertilizer containing free lime from feldspar and for a sufficiently low cost to make an industry based upon the method, worthy of consideration."

**Pot experiments with different potash minerals, D. N. PRANISHNIKOV** (*Landw. Vers. Stas.*, 77 (1912), No. 5-6, pp. 399-411, pls. 5; *abs. in Jour. Soc.*

*Chem. Indus.*, 31 (1912), No. 20, p. 1000).—In continuation of previous experiments (E. S. R., 26, p. 425) the author made comparative tests on a variety of crops of nepheline, muscovite, biotite, leucite, apophyllite, phillipsite, sanidine, microcline, eliolith, and mica schist.

The results show in general that while some of the aluminosilicates are tolerably good sources of potash, others are worthless for this purpose. The feldspar group is a poor source of potash for plants. The minerals tested appeared to stand in the following order as regards availability of potash: Nepheline, mica, biotite, phillipsite, muscovite, eliolith, leucite, apophyllite, sanidine, orthoclase, microcline. This was practically the order indicated by the solubility of the potash of the minerals in neutral salts (ammonium and barium chlorids).

To what extent can the potash of fine-ground feldspar be utilized by plants on moor soils? H. VON FELITZEN (*Ernähr. Pflanze*, 8 (1912), No. 19, pp. 225-232, figs. 6).—The results of the experiments here reported, which extended over a series of years, indicated as a rule very little effect from the potash of feldspar as compared with that of potash salts.

Comparative tests of phonolite, 40 per cent potassium salts, and kainit, M. ÖHME (*Deut. Landw. Presse*, 39 (1912), No. 67, pp. 740, 741).—Plat experiments on moor meadows during 1910 and 1911 indicated no beneficial results from applications of phonolite, whereas the 40 per cent potassium salts and kainit gave excellent returns.

Thomas phosphate meal. D. J. HISSINK (*Cultura*, 27 (1912), No. 288, pp. 315-317).—The requirements of the fertilizer law, as regards the composition, solubility, and physical constitution of Thomas meal as sold on the market in the Netherlands, are stated and briefly explained.

The agricultural value of electric slag, M. DE MOLINARI and O. LIGOT (*Ann. Gemblour*, 22 (1912), No. 10, pp. 567-572, figs. 2; *abs. in Engrais*, 27 (1912), No. 41, pp. 1138, 1139).—A brief account is given of pot experiments with oats on sand and soil to determine the relative fertilizing value of ordinary Thomas slag and slag made by a new electric process. The Thomas slag used contained 21.81 per cent of phosphoric acid soluble in mineral acids and 20.94 per cent soluble in 2 per cent citric acid. The two electric slags used contained, respectively, 5.12 and 6.76 per cent of phosphoric acid soluble in mineral acids and 1.56 and 1.38 per cent soluble in 2 per cent citric acid.

The results showed that on the basis of total phosphoric acid the electric slag gave results inferior to those obtained with Thomas slag. On the basis of phosphoric acid soluble in 2 per cent citric acid the results were about the same.

The assimilation of phosphatic fertilizers in the course of a rotation, A. MÜNTZ and H. GAUDECHON (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 4, pp. 257-260; *abs. in Rev. Sci. [Paris]*, 50 (1912), II, No. 5, p. 156; *Rev. Gén. Agron.*, n. ser., 7 (1912), No. 8, pp. 289-292; *Chem. Zentbl.*, 1912, II, No. 15, p. 1307).—The general conclusion reached from these investigations is that it is not advisable to apply large amounts of readily assimilable phosphatic fertilizers, with the expectation that the effect of such fertilizers will be extended over several years. On the contrary, the amount of such fertilizers should be in proportion to the needs of the crops during each season.

The assimilation of phosphoric acid by plants, A. MÜNTZ and H. GAUDECHON (*Ann. Sci. Agron.*, 4, ser., 1 (1912), II, No. 3, pp. 200-216; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 16, p. 787).—The rate of assimilation of phosphoric acid by maize, wheat, barley, rape, turnips, mustard, beans, peas, and lupines was determined in pot experiments with monocalcium phosphate (superphosphate), dicalcium phosphate (precipitated phosphate), and tricalcium phosphate.

The results show that assimilable phosphates become inactive in the soil the second or third year after application. Different species of plants vary in their capacity to utilize the phosphoric acid naturally present in the soil and therefore vary in the response that they make to applications of phosphatic fertilizers. The superiority shown the first year by superphosphate on account of its finer division and better distribution becomes very slight the second year and soon disappears, so that the three forms of chemically prepared phosphates used in these experiments showed about equal fertilizing values. See also the article noted above.

**The effect of cow dung on the availability of rock phosphate,** B. L. HARTWELL and F. R. PEMBER (*Rhode Island Sta. Bul.* 151, pp. 165-174, pl. 1).—“This bulletin contains the results of a pot experiment in which is ascertained the effect of finely ground rock phosphate, or floats, and cow feces or dung, used both singly and combined, on the growth of Japanese millet (*Panicum crus-galli*) and a succeeding crop of oats.

“Previous to drying, grinding, and mixing with the soil, the fresh dung was stored for about 9 months, not only by itself, but also in an intimate mixture with floats.” Portions were stored in a shallow pan, allowing free access of air. Other portions were packed in a bottle until the latter was completely filled, and stoppered so that only a small amount of air was present.

The soil used in the experiments had been limed and was deficient in phosphoric acid, but was supplied with optimum amounts of nitrogen and potash.

“The increase caused by the floats alone added to that caused by the dung alone was about equal to that obtained when both were applied together; and it made practically no difference whether the dung and floats were first brought together when they were added to the soil at the time of planting, or had been kept in a moist mixture during the previous 9 months.”

The results therefore indicate that practically no increase in available phosphoric acid resulted “from mixing fresh cow dung and floats together for a number of months before applying them to the land.”

**The action of calcium carbonate in the fertilizing of oats with monocalcium and dicalcium phosphate,** W. SIMMERMACHER (*Landw. Vers. Stat.*, 77 (1912), No. 5-6, pp. 441-471, fig. 1).—Pot experiments and chemical studies are reported which led to the conclusion that calcium carbonate does not reduce the fertilizing effect of monocalcium phosphate although it reduces the assimilation of phosphoric acid by the plant. In case of dicalcium phosphate, however, calcium carbonate strongly depressed both the yield and assimilation of phosphoric acid. The bearing of the results on the law of minimum as set forth by Mitscherlich (E. S. R., 25, p. 825) is discussed.

**The mechanism and fertilizing action of sulphur,** E. BOULLANGER and DUGARDIN (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 4, pp. 327-329; *abs. in Rev. Sci. [Paris]*, 50 (1912), II, No. 5, pp. 156, 157; *Rev. Vit.*, 38 (1912), No. 976, pp. 250-252; *Chem. Zentbl.*, 1912, II, No. 16, pp. 1392, 1393).—The favorable action of flowers of sulphur is attributed to its effect on the bacteria which break down the nitrogenous matter of the soil to ammonia, and also on the nitrifying organisms. In the presence of sulphur the plant is able to obtain a large amount of directly assimilable ammonium salts. Since the ammonia is formed exclusively from the nitrogenous matter of the soil, it is necessary to add organic nitrogenous fertilizers to the soil to counterbalance the rapid removal of nitrogen by plants under such conditions.

**Action of manganese oxid (MnO<sub>2</sub>) on organic nitrogenous compounds with reference to use of the oxid as fertilizer,** G. LEONCINI and C. PIERI (*Staz. Sper. Agr. Ital.*, 45 (1912), No. 3, pp. 224-244; *abs. in Chem. Zentbl.*, 1912, I, No. 20, pp. 1635, 1636).—It was found in these experiments that ammonium compounds

were not oxidized by manganese dioxid. It oxidized amids to nitric acid both in neutral and alkaline solutions at boiling temperature, but not at a temperature of 30° C. Amido acids and acid amids were not affected under these conditions. Uric acid and its derivatives xanthin and hypoxanthin were not oxidized. Only a trace of ammonia was observed. The oxid at ordinary temperatures under the conditions of this experiment did not convert organic nitrogen into nitric nitrogen.

**Indigenous manures of South India and their application.** W. H. HARRISON (*Depl. Agr. Madras Bul.* 65, 1912, pp. 11).—Among the manures whose composition and use are discussed in this article sunn hemp; indigo; various water weeds; oil cakes; ash of cane trash, cotton stalks, and paddy husks; indigo and rice wastes; fish fertilizers; and saltpeter; besides various animal and mineral fertilizers.

**Comparative trials of hand peat-litter machines** (*Finska Mosskulturför. Årsbok*, 16 (1912), No. 1, pp. 72-85, figs. 8).—Descriptions and trials of 6 peat-litter machines are given.

**Fertilizer statistics.** D. ZOLLA (*Rev. Gén. Sci.*, 23 (1912), No. 18, pp. 707-709).—Statistics are given of the production of nitrate of soda in Chile from 1830 to 1911; the consumption of nitrate in Europe and Egypt from 1900 to 1911, and in the United States from 1885 to 1911; the production of sulphate of ammonia in France from 1900 to 1911; the consumption of potash per unit area in different countries during 1911; the consumption of phosphates in France during 1900 to 1909; and the production of Algerian and Tunisian phosphates during 1899 to 1911.

**Fertilizers.** R. E. ROSE and L. HEIMBURGER (*Fla. Quart. Bul. Agr. Dept.*, 22 (1912), No. 4, pp. 157-167, 171-179).—An account is given of the fertilizer inspection during 1912, including analyses of fertilizers examined, with notes on laws and regulations and valuation of fertilizers.

**Fertilizer analyses.** H. B. McDONNELL ET AL. (*Id. Agr. Col. Quart.*, 1912, No. 57, pp. 40).—This bulletin gives tables showing analyses and valuations of fertilizers inspected from February to July, 1912, inclusive, and the text of the new fertilizer law, which will take effect February 1, 1913.

**Inspection of commercial fertilizers, season 1911 and 1912** (*Bul. [Miss. Dept. Agr. and Com.]* 7 (1912), No. 11, pp. 1, 2).—This is a report of analyses and valuations of fertilizers examined during October, 1912.

**List of fertilizer manufacturers and importers** (*Penn. Dept. Agr. Bul.* 220, 1912, pp. 39).—This list gives not only names and addresses of the manufacturers and importers, but names of the "brands of their fertilizers for which license to sell in Pennsylvania during 1912 was taken out prior to February 23, 1912." The text of the State fertilizer law is also given.

**The lime inspection law of Maryland** (*Id. Agr. Col. Quart.*, 1912, No. 56, pp. 3, 8).—The text of this law, which went into effect June 1, 1912, is given.

## AGRICULTURAL BOTANY.

**Studies on fungi for beginners.—II, Microscopic fungi.** G. LINDAU (*Kryptogamenflora für Anfänger. II, Mikroskopische Pilze.* Berlin, 1912, pp. VII+ (24)+276, figs. 558).—This gives directions for the microscopical study of the various groups of fungi, followed by synoptical keys and descriptions of genera and species of fungi belonging to the groups Schizomycetes to Basidiomycetes.

**Bacteria, yeasts, and molds in the home.** H. W. CONN (*Boston, New York, Chicago, and London, 1912, rev. ed.*, pp. VI+295, figs. 83).—This is a second edition of the author's popular work, which is designed for use in connection with courses in home economics and by those engaged in household manage-

ment. The general nature of molds, yeasts, and bacteria, and the action and use of beneficial forms are described. Chapters are given on the preservation of food, use of preservatives, canning, etc., as well as on disease bacteria, disinfection, etc. Directions for laboratory experiments to be carried on in connection with courses are also given.

**A laboratory guide in soil bacteriology**, J. G. LIPMAN and P. E. BROWN (1911, pp. IV+87, chart 1).—This little book consists of 55 exercises on soil bacteriology, and is designed by the authors to follow courses in general bacteriology and technique. Chapters are given on the preparation of media, methods of determination, and a descriptive chart for the recording of cultural and morphological characteristics of organisms.

**Fungus flora of the soil**, C. N. JENSEN (*New York Cornell Sta. Bul.* 315, pp. 415-501, figs. 35).—This gives the results of a study of the fungus flora of the soil, made as a partial fulfillment of the requirements for the degree of doctor of philosophy in Cornell University. After a historical sketch of the subject the author describes methods of taking soil samples and isolating and cultivating the organisms. The major portion of the bulletin is taken up with taxonomic descriptions of the different forms.

The fungus flora of the soil was found to consist of obligate saprophytes and facultative parasites, the former being by far the more abundant. According to the author a fungus should not be considered as belonging to the soil flora unless it has been directly isolated or has been shown under control experiments to live in the soil. In this connection he demonstrated that *Phoma beta*, one of the causes of root rot of sugar beets, winters on the seed balls and not in the soil, while *Pythium debaryanum* and *Aphanomyces laxus*, other organisms which attack the sugar beet, winter as saprophytes in the soil and not on the seed balls.

The presumable facultative parasites and the obligate saprophytes determined number 132 species and varieties, many of which are recognized as a cause of injury to economic plants.

A study was made of the effect of sulphur on the fungus flora of the soil, but 3 months after its application the soil yielded the same species of fungi as did samples which had received no application.

**Bacteria and other fungi in relation to the soil**, D. RIVAS (*Contrib. Bot. Lab. Univ. Penn.*, 3 (1911), No. 3, pp. 243-274, fig. 1).—The author investigated the numbers and activities of about 28 kinds of bacteria, 2 of cocci and 10 of molds found in soils at 12 stations, and reports the following results and conclusions:

The bacterial contents of the soil were found to vary according to season, being least from November to February and increasing thereafter to a climax in September or October. These soils are found to be very rich in bacteria producing diastatic, inverting, and proteolytic ferments which are especially adapted for digesting carbohydrates and proteids and which, by changing them into glucose and peptones, respectively, render this raw organic matter into assimilable substances. There is thought to be good reason to assume that this already elaborated food material is, through the agency of bacteria, thus made ready for absorption by the root system and for the nutrition of the plant. It is held, therefore, that not alone are water and salts in solution taken up by the root system of the plant but also already elaborated food, such as glucose, and further that such food, in addition to supplying energy and nourishment to the plant, may become a constituent of the protoplasm and may form organized structures, waste products, and reserve materials, this whole process thus resembling in essentials the process of assimilation in animals. Photosynthesis or auto-assimilation by the plant is not thought to explain all

the facts of plant nutrition and in all probability the heterotrophic nutrition suggested by the author's experiments is to some extent effective.

**Biological and toxicological studies upon *Penicillium puberulum*.** C. L. ALSBERG and O. F. BLACK (*Proc. Soc. Expt. Biol. and Med.*, 9 (1911), No. 1, p. 6; *abs. in Bot. Centbl.*, 119 (1912), No. 21, p. 525).—This fungus, when grown in pure culture upon Raubin's solution, produces a new organic acid termed penicillic acid and thought to belong to the general class called lichen acids. It is stated to be moderately toxic, antiseptic in its action, and a protoplasmic poison. Since lichens are symbiotic forms, composed of fungi and algae, the finding of this type of substances in the pure culture of a fungus makes it seem probable that in lichens, the lichen acids are the products of the fungus metabolism, and not of that of the algae.

**Some conditions influencing nitrogen fixation by aerobic organisms.** W. B. BOTTOMLEY (*Proc. Roy. Soc. [London]*, Ser. B, 85 (1912), No. B 581, pp. 466-468).—A study has been made of *Azotobacter* and *Pseudomonas* separately and in combination to determine a suitable form of sugar for the growth of these nitrogen-fixing organisms.

Under usual conditions mannite is found most efficient for the growth of *Azotobacter* and maltose for *Pseudomonas*. The author's investigations, however, show that dextrin is about as efficient as maltose for *Pseudomonas* and as mannite for *Azotobacter*, while for a mixed culture of the two organisms it is much more efficient than a mixture of maltose and mannite. For both of these organisms the author recommends a simple and effective nutrient medium obtained by adding to distilled water 1 per cent dextrin, 0.2 per cent dipotassium phosphate, 0.02 per cent magnesium sulphate, and 0.4 per cent basic slag.

**The influence of temperature on the movement of zoospores of *Chlamydomonas*.** P. DESROCHE (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 19, pp. 1244-1247, fig. 1; *Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), Nos. 17, pp. 748-750; 18, pp. 793-795, fig. 1).—Continuing previous studies on *Chlamydomonas* (E. S. R., 26, p. 431), the author found that the range of temperature within which movement of the zoospores is possible extends from the freezing point on the one hand to about 40° on the other, provided the containing water be very slowly warmed. Nearly all, however, became inactive between 30 and 32°. This fact and the facts of individual differences of endurance at given temperatures, of behavior on slower or more rapid warming, and of recovery on cooling make it difficult to fix a maximum limit of temperature for the activity of *Chlamydomonas*.

If the water containing the zoospores be very slowly warmed to 39° and there maintained, in about 15 minutes a marked degeneration of the cilia is observable which results in their complete disappearance in about 1 hour. The author remarks that the degeneration of cilia in this case is quite comparable with that observed in the case of *Pythium* and *Saprolegnia*, very different organisms from the one here studied.

**Studies in seeds and fruits.** H. B. GUPPY (*London*, 1912, pp. XII+528, figs. 6).—This book is the result of a study begun on the rest period of seeds and includes observations on some of the factors which are concerned in the rest period and germination of seeds, the relation of seeds to fruits, etc. Among the factors discussed are permeability, hygroscopicity, rôle of shrinking and swelling of seeds, homologies of fruits, dehiscence of fruits, relation of number of seed to weight and size of the fruit, abortion of ovules, seed coloration, and rest period of seeds.

**The influence of organic acids and glucose on the respiration of seeds during their swelling.** Mlle. G. PROMSY (*Rev. Gén. Bot.*, 24 (1912), No. 283, pp. 313-318).—In a previous paper (E. S. R., 25, p. 222) the author showed the

effect of citric acid absorbed by the seeds of tomato, pepper, maize, etc. In the present paper an account is given of investigations with beans and peanuts to determine the effect of citric acid and glucose solutions on the respiration of the seed.

It was found that the presence of these substances in a liquid medium where germinating seeds have begun to swell modifies the respiratory quotient, sometimes increasing and other times diminishing it, according to the variety of the seed and to the substance used. When the substance was acid there was always an increase, but when glucose was added there was an increase with some seeds, such as the bean, and a diminution with others, as was the case with the peanut.

**Tannin in the seed coats of barley.** A. REICHARD (*Ztschr. Chem. u. Indus. Kolloide*, 10 (1912), No. 5, pp. 214-219; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 596, II, pp. 592, 593).—In a previous publication Brown (E. S. R., 21, p. 126) showed that a membrane in the testa of the barley grain exerts a selective action on dissolved substances, inasmuch as only certain of them can pass through it into the seed. The present author has carried on a series of investigations and has found that there is a kind of tannin in the seed covering of barley and that there is an undoubted parallelism between the power of a substance to dissolve this material and its ability to penetrate the membrane.

The investigations were made by a variety of methods, which included the direct action of different substances on sections of the barley grain with subsequent examination of the membrane for tannin, and also adding various substances to ordinary tannin in a test tube and observing the effects. There appears to be some evidence that the tannin in barley is associated with a proteid, and the action of different substances on a compound of protein and tannin was investigated.

The author ascribes the results obtained to a solvent action on the tannin, thus permitting diffusion, or in some cases to a coagulating effect of the reagents on the tannin complex, which prevents diffusion.

**Pentosans and methylpentosans in seeds of *Glycine hispida* and *Phaseolus vulgaris* during germination.** K. MIYAKE (*Jour. Col. Agr. Tohoku Imp. Univ.*, 4 (1912), No. 8, pp. 327-335).—From a study of germinating bean seeds the author concludes that pentosans and methylpentosans are not ordinarily used as reserve or nutrient material in germination, being utilized rather to form skeletal structures, but that in case of exhaustion of the more readily available materials these carbohydrates are made to supply the usual offices of such substances, methylpentosans in the larger quantity of the two.

**The artificial nourishment of seedlings.** W. ZALESKI and N. TUTORSKI (*Biochem. Ztschr.*, 43 (1912), No. 1-2, pp. 7-9).—The authors experimented with the axial parts of newly sprouted peas, sterilized and kept in darkness for 20 days in Knop's solution with addition of carbohydrates or in Knop's solution with a small amount of calcium sulphate to which was added either a nitrate, ammonium phosphate, asparagin, or crushed cotyledons of peas.

In carbohydrates these stems showed remarkable increase in size and dry weight, saccharose taking the most and galactose the least part in building new material. Nitrates, ammonia, and asparagin all gave considerable increase in nitrogenous materials, but their utilization is claimed to be indirect, the nitrates being first reduced and the nitrogen built into ammonia, later forming amino acids. Asparagin is thought to act in some small part directly in the formation of new nitrogen compounds. Ammonia is not thought to be directly elaborated into nitrogen products.

Investigations on the nourishment of seedlings with amino acids are still in progress.

**Effect of asparagin on absorption and growth in wheat.** J. J. SKINNER and J. H. BEATTIE (*Bul. Torrey Bot. Club*, 39 (1912), No. 9, pp. 429-437, pl. 1).—During the progress of studies of the organic matter in soils, experiments have been carried on with a number of organic compounds to determine their effect on plant growth. In the present paper an account is given of experiments on the effect of asparagin on the growth of wheat seedlings in culture solutions containing nutrient salts.

When the plants had grown for several days it was noticed that the asparagin cultures were better developed, the seedlings having broader leaves and longer and better developed roots. The effect of asparagin was more marked in the cultures containing potash and phosphate than in those which contain potash, phosphate, and nitrate.

This led to studies under control conditions which indicated that asparagin can be utilized for plant synthesis. The effect of the asparagin decreased with increasing quantities of nitrate, so far as additional effect on growth is concerned, but it was found to have a conserving effect on the nitrate left in the solution during the time the plants were growing.

**Studies on the carbohydrates and nitrogen-containing bodies in grape leaves.** N. T. DELEANO (*Hoppe-Schuler's Ztschr. Physiol. Chem.*, 80 (1912), No. 1, pp. 79-94).—In continuation of previous work (E. S. R., 25, p. 523), the author reports that by analysis of dried grape leaves gathered in September he was able to demonstrate the presence therein of dextrose, levulose, inosit, glutamin, and cholin, but not of sucrose, amino acids, alloxuric bases, histidin, arginin, or betain. A bibliography is appended.

**Phosphoric acid and nitrogen in alcoholic extracts of leaves.** J. SESSL (*Ztschr. Landw. Versuchsiv. Österr.*, 14 (1911), No. 6, pp. 886-893; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 593, II, p. 288).—The author's analyses of leaves of horse chestnut, maple, oak, mock orange, and knotweed made monthly during the growing season showed a fairly constant decrease in total phosphoric acid and nitrogen, this diminution being usually more marked in the older leaves. The ratio of phosphorus to nitrogen also usually showed a decrease, notably in case of horse chestnut and especially just before leaf fall.

**The influence of phosphates on the post-mortem respiration of plants.** W. ZALESKI and ELISABETH MARX (*Biochem. Ztschr.*, 43 (1912), No. 1-2, pp. 1-6).—Continuing previous studies (E. S. R., 26, p. 729), the authors experimented with grain and pea seeds, pulverized and kept for varying periods in solutions of acid, alkaline, and neutral reaction.

It was found that, in general, acids decreased and alkalis increased the evolution of carbon dioxide. The latter effect, occurring (as in case of edestin) in absence of hydroxy, is pointed to as an obstacle to acceptance of the views of S. Kostytschew and A. Scheloumow (E. S. R., 26, p. 627).

It is claimed that some part is played by the phosphates contained in the seeds tested. It is suggested also that the effect of alkaline phosphates is in part due to the protection given by the alkalinity against the depressing effect of acid-reacting substances (as casein) on the evolution of carbon dioxide, thus favoring a greater net result as regards this product.

**Contribution to the study of circulation.** **Studies on the sweet potato (*Ipomœa batatas*).** B. H. A. GROTH (*New Jersey Stas. Rpt. 1910*, pp. 283-286, pls. 2, fig. 1).—In continuation of a previous report (E. S. R., 25, p. 431), an account is given of the circulation in the sweet potato as influenced by the rooting of the plants at the nodes. In addition to this work, an investigation with the object of tracing the movement of reserve starch in the circulation of a many-rooted sweet potato plant was begun. It was found that the storage starch in a sweet potato plant with the normal direction of the water current is

intercepted in its course by the first roots basal to the leaf from where it starts, and does not go beyond it.

The bearing of the results of these experiments on the cultivation of the sweet potato is quite evident, as they show that any portion of a many-rooted sweet potato plant may draw water from the roots most favorably situated, which are those in the main hill, so that whenever a drought occurs the rooted branches will draw water from the main hill. Every rooted joint of any branch intercepts all the starch brought from all the leaves beyond it and allows none to pass to the main hill. In a dry time a rooted branch may feed upon the main root, but in the best growing time it does not help the crop of the main plant in the least.

**The stomatograph, W. L. BALLS** (*Nature* [London], 87 (1911), No. 2180, p. 180; *Proc. Roy. Soc.* [London], *Scr. B*, 85 (1912), No. B 576, pp. 33-44, figs. 5).—The appliance here described and discussed is said to be a self-recording modification of Darwin's porometer (E. S. R., 27, p. 222), indicating changes in stomatal aperture by recording variations in the quantity of air forced through a leaf. It is claimed to be extremely easy to use, independent of weather changes, and especially adapted to outdoor conditions such as are met with in agricultural and ecological studies. Records obtained with Egyptian cotton indicated that this instrument may be of great utility in the study of purely economic matters connected with irrigation, and it is thought also that it may replace aspirators for many kinds of scientific research. The results of some studies on the behavior of stomata are given, and the significance of these stomatal changes as related to carbon dioxide assimilation in the growth of the plant is also discussed.

**Photosynthesis and stomatal aperture, W. L. BALLS** (*Nature* [London], 89 (1912), No. 2231, p. 555).—In the paper noted above the author, having found that Egyptian field cotton plants showed stomatal opening practically only from 6 a. m. to 12 m., reaching a maximum about 9 a. m., expressed the expectation that (1) this afternoon closure might be found to provide a limiting factor on photosynthesis by restricting the inward diffusion of carbon dioxide; and (2) since the theoretical possibilities of carbon dioxide assimilation have probably never yet been approached and since the stomata are wide open for an hour or two in the morning, record values in carbon dioxide assimilation might be obtained at the times of such maximum aperture.

The present brief report states that both these expectations have been fulfilled. It was found that assimilation was very greatly reduced, if not inhibited entirely, during the afternoon by the closing of the stomata. Some other data obtained are reported in this connection.

**Reversible changes in permeability produced by electrolytes, W. J. V. OSTERHOUT** (*Science, n. ser.*, 36 (1912), No. 924, pp. 350-352).—Different opinions being held regarding the property of permeability of the cell, the author has investigated it to determine whether there are reversible changes which involve no injury and which may form a normal part of the activity of the cell. If such changes occur it is believed that they may control the course of metabolism.

Disks were cut from living tissue of the fronds of common kelp and their electrical conductivity in various solutions determined. It appeared that the permeability may be greatly decreased and then restored to the normal several times on five successive days without any trace of injury. Experiments with dead tissues, killed by heat or formalin, showed that the results were due entirely to the living cells.

It is concluded that it is possible to cause rapid and large changes in permeability by means of electrolytes, that these changes may consist in

either an increase or a decrease in permeability, and that within wide limits they may be completely reversible and entirely devoid of injurious effects.

The oxidases of *Cytisus adami*, F. KEEBLE and E. F. ARMSTRONG (*Proc. Roy. Soc. [London], Ser. B, 85 (1912), No. B 581, pp. 460-465*).—A study has been made of *C. adami*, which bears yellow, buff, and purple flowers, to determine from its oxidases the origin of this so-called graft hybrid. This plant, which is supposed to have been derived from *C. purpureus* budded on *C. taburnum*, has been considered a periclinal chimera, that is, a dual organism composed externally of one species and internally of another.

The author's investigations on the oxidases confirm Baur's hypothesis, the oxidases of the flowers produced from the different portions of the plant showing different reactions. There was also found evidence to support their own claim that oxidases may migrate from cell to cell. It is believed that certain tissues of the vascular system may be regarded as secretors of oxidases which have among other functions the formation of flower pigments.

The primary color factors of *Lychnis* and color inhibitors of *Papaver rhœas*, G. H. SHULL (*Bot. Gaz., 54 (1912), No. 2, pp. 120-135*).—The main substance of this report has already been noted (E. S. R., 26, p. 827), but later studies have resulted in discoveries necessitating the withdrawal of *L. dioica* for the present as an example of dominant white, apparently without affecting, however, the general considerations as originally presented. A bibliography is appended.

Cell number in the fruit of the prairie berry, B. H. A. GROTH (*New Jersey Stat. Rpt. 1910, pp. 287-291, pls. 2*).—The results of a study of heredity of fluctuation as shown in the prairie berry or garden huckleberry, a cultivated variety of *Solanum nigrum*, are given. Considerable variation in the number of cells in the fruit had been previously noted, and the fruits of several plants grown from the seed of a single fruit were examined and the variation observed. While the averages appear consistent and instructive, the author holds that the variation in individual plants was so great that they can not be considered conclusive.

Observations concerning evolution, derived from ecological studies in New Zealand, L. COCKAYNE (*Trans. and Proc. New Zeal. Inst., 44 (1911), pp. 1-50, pls. 8, figs. 3*).—The results of an ecological study of the plants of New Zealand are given and the bearing of some of the facts upon evolution of species is discussed. The main object of the paper is to supply material of a botanical nature to students of evolution. A bibliography of the subject is appended.

## FIELD CROPS.

[Field husbandry experiments], J. E. HOWITT and C. A. ZAVITZ (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 37 (1911), pp. 46, 47, 51-54, 175-248, figs. 11*).—The work of 1910 has been previously noted (E. S. R., 25, p. 527).

A list of the weeds attracting most attention during the year is followed by descriptions of the Russian thistle (*Salsola kali* var. *tenuifolia*), crab or finger grass (*Digitaria sanguinalis*), water hemlock or spotted cowbane (*Cicuta maculata*), and wood horsetail (*Equisetum sylvaticum*), together with brief notes on their eradication. Spraying white cockle with a 30 per cent solution of iron sulphate prevented seed production and spraying ragweed in oats with a 20 per cent solution gave profitable results. Samples of red and alsike clover and alfalfa seed were tested for purity and the results are reported.

Weather conditions in 1911 are reviewed and a table is given showing the precipitation for April to September, inclusive, in each of the past 12 years.

The average yields per acre in a comparison of barley, emmer, oats, hull-less barley, spring wheat, field peas, and spring rye, mentioned in the decreasing order of yield, ranged from 2,672 lbs. to 1,709 lbs. of grain for the past 11 years. Results with 35 varieties of cereals and potatoes grown continuously on the same farm from 17 to 23 years show that fully 80 per cent of the varieties gave considerably larger yields during the latter as compared with the earlier part of the period. In this connection, suitable crop rotations are discussed and attention is called to the importance of growing the most profitable varieties.

Experiments on the influence of seed selection with different crops in progress from 6 to 9 years are described and a table is presented showing that in every instance the large plump seed gave a greater yield of grain per acre than small, shrunken, or broken seed. The crops entering into this experiment were spring and winter wheat, oats, barley, and peas, and exactly the same number of seeds were used in the different plats. Plant selection as a factor in crop improvement is dwelt upon, and the O. A. C. No. 21 barley and the O. A. C. No. 72 oats, originated at the college, are described. The O. A. C. No. 21 barley is a selection from Mandscheuri barley, which has long been the leading variety in Ontario but which is being supplanted at the present time by the new strain, which 4 years' cooperative experiments in Ontario have indicated to be the better of the two in yield of grain per acre, freedom from rust, and both length and strength of straw. The O. A. C. No. 72 oats, a selection from the Siberian variety, was distributed during the past year and the results secured have shown it to be a very promising variety when compared with other sorts such as Lincoln, Regenerated Abundance, and Siberian. It is pointed out that the distribution of new varieties is greatly facilitated by the Ontario Agricultural and Experimental Union, which numbered in 1911 4,490 experimenters.

When 9 different proportions of oats and barley were used in combination the mixture of 4 pks. or 34 lbs. of oats and of 4 pks. or 48 lbs. of barley per acre gave the highest results in a test of 6 years, as well as in a second test of 5 years. This mixture surpassed in yield of grain per acre any one of 16 other combinations. Different varieties of farm crops grown in combination with barley for 5 years, the rate of seeding being 1 bu. of each per acre, showed that in every single instance the resulting crop was over 50 per cent barley. The lowest percentage of barley was secured where Guy Mayle hull-less variety was used with Siberian oats, and the highest percentage where Mandscheuri barley was mixed with common flax. The influence of the Mandscheuri barley was more pronounced than any of the two-rowed barleys used in combination with oats. In studying the percentages of grain produced by different mixtures, it was observed that six-rowed barley and oats have a strong tendency to reproduce themselves even when sown in combination with a larger number of other leading varieties and classes of farm crops.

Work in combating loose smut in oats and stinking smut in wheat was continued and a number of different treatments were compared. Early Ripe oats proved practically immune to the attacks of smut spores, while Black Tartar and Siberian were quite badly infested in 1911. The results of all the experiments showed that the greatest yields of both winter wheat and oats per acre were secured from the grain immersed in a solution of 42 gal. of water and 1 pt. of formalin for 20 minutes. This treatment was the most effective in completely preventing smut in a 5-year test.

The average yield of winter barley grown at the college for 15 years was 54.8 bu. per acre, the average weight being 47.8 lbs. per measured bushel.

Within the past 18 years winter barley has been completely killed out on three occasions, while during some of the other winters it was partially killed.

In comparing the average results of varieties of oats, the percentage of hull as affecting the quality of the grain was taken into account. It is pointed out that Early Dawson oats, having an average weight of 37.55 lbs. per measured bushel in a 6-year test is not as valuable as the Daubeney variety which had a weight of only 34.29 lbs. per measured bushel, but which had nearly 10 per cent less hull. Observations made on the stooling of oats for 3 years indicated a variation in the average number of stools from 7 in Storm King and Tartar King to 18 in Joannette, Burt, and Regenerated Abundance. American Banner and Siberian occupied an intermediate position. It is stated that in general heavy stooling varieties appear to adapt themselves better to conditions than varieties which stool very little.

Experiments with potatoes led to the conclusion that good-sized tubers of good shape should be selected for seed and that the sets should vary in size from 1 to 2 oz. and have from 2 to 4 eyes each. The yields from level and from hilled cultivation have shown practically no difference in experiments over a series of 10 years. In wet seasons, hilled cultivation and in dry seasons level cultivation gave the best results. In experiments with Bordeaux mixture in combating potato blight, the best results were obtained from spraying 3 times on top and underneath the vines. This treatment gave larger yields per acre than when the potatoes were sprayed from 5 to 6 times on top of the vines.

During the past 6 years, Japanese Panicle millet, Japanese Barnyard grass, and Hungarian grass were sown at intervals of about 2 weeks beginning May 15 and ending August 1. The highest average yield for the 3 varieties, 8.28 tons of green crop per acre, was obtained from the seeding made June 1.

The average results for the past 11 years with a number of miscellaneous leguminous crops grown for green fodder show that hairy vetch ranked first in green fodder production per acre with a yield of 7.1 tons, being followed by Grass peas, Early Yellow soy beans, and Wonderful cowpeas with 6.8, 6.5, and 4.9 tons per acre respectively. In numerous experiments with red clover, it was found that land, after growing this crop, was more easily plowed and was in a more friable condition than land on which timothy, meadow fescue, or orchard grass had been grown. Tests made with alfalfa resulted in an average yield of 20.41 tons of green crop and 4.9 tons of hay per acre for a period of 14 years. Canadian Variegated alfalfa has proven very hardy and is considered worthy of special attention in the Province of Ontario.

Good results were secured from a pasture mixture consisting of 51 lbs. of oats, 30 lbs. of Early Amber sugar cane and 7 lbs. of red clover per acre. This mixture was used for a temporary pasture of 1 year's duration. For permanent pasture 4 lbs. of orchard grass, 4 lbs. of meadow fescue, 3 lbs. of tall oat grass, 2 lbs. of meadow foxtail, 2 lbs. of timothy, 2 lbs. of alfalfa, 2 lbs. of alsike clover, and 2 lbs. of white or Dutch clover per acre are recommended in the light of experience for more than 20 years' work in testing different varieties of grasses and clovers for this purpose.

The higher yields obtained in variety tests are indicated in the following table:

*Summary of the more notable yields secured in variety tests.*

Crop and variety.	Number of varieties tested.	Period of test.	Average yield per acre.	Crop and variety.	Number of varieties tested.	Period of test.	Average yield per acre.
Barley (Mandsch- eur).....	7	Yrs. 5	Bu. 76.60	Broom corn (Early Japanese).....	3	Yrs. 9	Bu. 22.40
Barley (Imported No. 5591 Iowa)...	6	5	64.39	Corn (Early Cali- fornia Flint)....	12	5	59.70
Barley (Guy Mayle)	6	5	45.94	Potatoes (Davies Warrior).....	57	5	239.40
Oats (Daubney)...	30	6	79.89	Mangels (Giant Eckendorf)....	12	5	30.68
Wheat (Dawson Golden Chaff)....	14	16	54.10	Sugar beets (Ren- nie Jumbo)....	12	5	24.80
Wheat (Carleton)...	15	5	32.44	Swedes (Keepwell).	14	5	20.02
Wheat (Roumania)	7	5	33.35	Carrots (Steele Im- proved Short White).....	6	6	28.00
Wheat (W i l d Goose).....	3	19	37.50	F o d d e r   c o r n (Eureka).....	47	5	24.68
Emmer (common)...	3	10	Lbs. 2,872	Sorghum (Orange sugar cane)....	9	13	18.26

Millet (Siberian)...	7	8	51.80				
Sunflowers (Mam- moth Russian)...	3	13	76.61				

[Forage and cover crops], F. C. MINKLER (*New Jersey Stas. Rpt. 1910, pp. 51-57*).—Good results are reported from the use of oat and pea forage run through the ensilage cutter in a slightly wilted condition and placed in the silo. In this way silage in prime condition was provided for dairy cows during the entire summer season and the milk flow was maintained during the period of hot weather and the lack of green forage.

A total of 98 tons, or an average of 5.9 tons per acre, was secured from 16½ acres of alfalfa at the station. A new seeding of 10 acres yielded 30.425 tons of cured hay mowed May 30. The manner of making this seeding on August 24 of the preceding year is described in detail.

The yield of 9 tons of forage is reported from an acre of ground seeded in September, 1909, with 50 lbs. of rye and 20 lbs. of vetch drilled in rows 8 in. apart. The yield of hay from 9 acres of oats and peas was approximately 3 tons per acre, and fertilizer tests continued in this connection confirmed previous results, showing that basic slag supplies phosphoric acid more economically than ground bone and acid phosphate. The use of different cover crop mixtures, the principal one consisting of 40 lbs. of wheat and 25 lbs. of winter vetch per acre, seeded just prior to the last cultivation of corn during the latter part of July, is reported.

The seed-corn situation, C. P. HARTLEY (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 95, pp. 13, figs. 2*).—The general seed-corn situation in the spring of 1912 is reviewed and means of preventing such situations are suggested.

Results secured in 2 series of 5-year tests made by the Office of Corn Investigations and 28 experiment stations for the purpose of observing the value of home-grown seed showed that a variety stood high or low in rank according to its adaptation or lack of adaptation to the locality in which the test was made. In one particular instance, a variety native of Sabina, Ohio, was taken 50 miles north and grown for 5 years at Sunbury in that State. Equivalent lots of Sabina-grown seed and Sunbury-grown seed were then tested at both points.

At Sabina, the Sabina-grown seed produced better by 47 per cent, while at Sunbury, the Sunbury-grown seed produced better by 11 per cent.

Germination tests made by the Seed Laboratory of this Department of 1,708 samples of seed corn from 17 of the principal corn-growing States and intended for use in the spring of 1912 gave an average germination of 81 per cent, the lowest germination for the different States ranging from 0 to 30 per cent. The seed corn sent from 7 of these States contained samples with 0 per cent of germination. Tests made by this laboratory of 73 samples of seed corn from 8 different States gathered and dried early by the Office of Corn Investigations gave an average germination of 98.1 per cent.

The care of seed corn is discussed and the results of experiments to demonstrate the possible profits from the good preservation of seed corn are reported. It is stated that 17 tests of seed corn dried and stored in a seed-corn dry house and of seed corn stored in the crib gave figures showing an average increase in yield of 5 bu. per acre in favor of the special storage. A more extensive field test along the same line gave similar results.

**Inheritance in corn.** H. K. HAYES (*Connecticut State Sta. Rpt. 1911, pt. 6, pp. 407-425, pls. 8*).—This article summarizes in a popular manner the results of corn breeding work carried on by the station for the last 6 years and previously noted (*E. S. R.*, 17, p. 857; 25, pp. 736, 737). The way of detecting and culling out the accidental hybrid seed is described and the manner in which desirable qualities are inherited is pointed out. In discussing crosses showing dominance, the appearance of the crosses, the production of the seed of pure varieties, and the inheritance of characters is considered. The behavior of crosses not showing dominance is also discussed and notes are given on abnormalities, including dwarf forms, divided ears, and irregularity in the rows of seeds.

**Results of cotton experiments in 1911.** O. F. COOK (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 96, pp. 21*).—This bulletin reports the progress in experiments with cotton and summarizes briefly the principal conclusions, especially those affecting general problems of breeding and crop production.

Attention is called to the utilization of improved varieties of American Upland cotton bred by this Department for the improvement of the cotton industry, and to the results secured in Texas and other southwestern States with acclimatized new types of Upland cotton introduced from weevil-infested regions of Mexico and Central America. One of the new varieties from Mexico, known as Durango, was found to be the most promising Upland long-staple cotton for irrigated districts in that region. The advantages to be gained from cooperative organization on a community basis for the production and marketing of a single superior variety of cotton are pointed out.

Improved methods of selection in which the value of distinctive characters by which the plants may be recognized in the field is taken into account, and better methods of distributing select varieties to avoid waste and to encourage the production of superior fiber on a community basis were devised and are described in detail. Cultural methods are suggested for avoiding malformations of young seedlings which often delay the development of the plants and reduce the yield. Several methods of utilizing superior first-generation hybrids between Egyptian and Upland varieties of cotton, including the propagation of such hybrids from cuttings, are reported as being under test.

Experiments have shown the possibility of controlling the development of vegetative branches by thinning the plants gradually and restricting the supply of water in the early stages of growth. This control, it is pointed out, facilitates cultivation and picking and favors greater production.

It was observed that the Egyptian type of cotton was less susceptible to the shedding of the buds and young bolls than the Upland cotton and that the differences in habits of growth and methods of picking render the Egyptian cotton superior to the Upland type as a family crop. It is believed that the successful production of Egyptian cotton in Arizona and southern California does not justify expectations of similar results in Texas where the conditions are essentially different and where the Durango variety is preferable for the irrigated districts.

**Cotton crop of the United States, 1790-1911**, G. K. HOLMES (*U. S. Dept. Agr., Bur. Statis. Circ. 32, pp. 9*).—The production, value, domestic exports, net imports, and consumption of cotton in the United States for the years 1790 to 1911, inclusive, are reported in tabular form. Prior to 1867 no figures for the average yield per acre, and prior to 1869 no data for the value of lint, are reported.

**Hop crop of the United States, 1790-1911**, G. K. HOLMES (*U. S. Dept. Agr., Bur. Statis. Circ. 35, pp. 8*).—In so far as the data are available the production, value, domestic exports, imports, and consumption of hops for the United States from 1790 to 1911, inclusive, are given in tables.

**Potato culture**, H. J. EUSTACE (*Michigan Sta. Circ. 15, pp. 4, fig. 1*).—Popular notes on the culture of potatoes are presented.

**Potato spraying experiments, 1902-1911**, F. C. STEWART, G. T. FRENCH, and F. A. SIBBINE (*New York State Sta. Bul. 349, pp. 99-139*).—This bulletin gives a detailed account of potato spraying experiments conducted in 1911 and summarizes the results of similar experiments made during the 9 years preceding and already noted (*E. S. R., 25, p. 442*).

The main experiments were conducted at Geneva and Riverhead, Long Island, and at each place one series of plats received annually 3 sprayings of Bordeaux mixture and another series 5 to 7 sprayings. At Geneva, 3 sprayings resulted in an average increase of 69 bu. per acre for the 10 years as compared with 97.5 bu. per acre for from 5 to 7 sprayings. In the Long Island experiments, 3 sprayings gave a 10-year average increase of 25 bu. per acre and from 5 to 7 sprayings an increase of 45.7 bu.

The results of experiments made by farmers during 9 consecutive years to determine the actual profit in spraying potatoes under farm conditions showed an average increase of 36.1 bu. per acre in favor of spraying. The total expense of spraying in these experiments was \$4.74 per acre and the net profit \$14.43 per acre. In 205 experiments carried out entirely by farmers themselves over a period of 7 years, the average increase in yield was 54.3 bu. per acre.

Spraying thoroughly when the plants are from 6 to 8 in. high and repeating the operation at intervals of from 10 to 14 days throughout the season is recommended.

**Ten years of potato spraying**, F. H. HALL (*New York State Sta. Bul. 349, popular ed., pp. 11*).—This is a popular edition of the above.

**A preliminary report on rice growing in the Sacramento Valley**, C. E. CHAMBLISS (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 97, pp. 10, pls. 4*).—Tests with 300 varieties of rice were begun in 1909 in the Sacramento Valley on a black adobe soil of a close compact structure. The seed of each variety was planted with a drill to a depth of 1½ to 2 in. at the rate of 80 lbs. per acre on plats consisting of 4 rows a rod each in length and 7 in. apart. In 1910, a selection of 13 varieties from the 300 was tested on ½-acre plats. The yields for the different varieties ranged from 23.1 to 154 bu. per acre and the growing season from 142 to 193 days. In another test in 1910 in which the yield was estimated upon the actual yield from plats ½-acre in size the Wataribune (G. I.

No. 1561) and the Shinriki (G. I. No. 1642) varieties yielded 113.7 and 137.2 bu. per acre respectively.

It was found that in the Sacramento Valley the rices under test required a longer time to mature and produced smaller plants than when grown on the plains of the Gulf coast, but that they exhibited a greater capacity for tillering with resultant larger yields. The Honduras and Shinriki varieties (G. I. Nos. 1643 and 1642), the leading commercial rices of the United States, exceeded in this test the maximum yields produced on experimental plats in Louisiana and Texas. Of the two, the Shinriki is considered better adapted to the Sacramento Valley. It is pointed out that the Wataribume, the Oiran, and the Shinriki varieties produced good crops but that earlier maturing varieties of good quality, though producing less per acre, may be more remunerative for this locality. Suggestions as to the methods of culture are given and the statement is made that the results of the 2 years' work indicate the possibility of rice culture in the Sacramento Valley.

**Rice crop of the United States, 1712-1911,** G. K. HOLMES (*U. S. Dept. Agr., Bur. Statis. Circ. 34, pp. 11*).—Tables are given showing in so far as data were obtainable the production, value, domestic exports, imports, and consumption of rice for the United States for the years 1712-1911, inclusive.

**Tobacco crop of the United States, 1612-1911,** G. K. HOLMES (*U. S. Dept. Agr., Bur. Statis. Circ. 33, pp. 12*).—Data regarding the production, value, domestic exports, net imports, and consumption of tobacco in the United States from 1612-1911, inclusive, are given in tables.

**Tobacco report, July 1, 1912,** J. P. KILLEBREW (*U. S. Dept. Agr., Bur. Statis. Circ. 38, pp. 7*).—The acreage of tobacco in the United States July 1, 1912, by States and districts is reported in tables and the condition of the crop at this date is described. The 1912 area of cigar-leaf tobacco is given at 172,400 acres against a final estimate of 177,400 acres in 1911, and the acreage of the chewing, smoking, snuff, and export type is reported at 1,012,300 acres as compared with a final estimate of 819,500 acres in 1911.

**Growing winter wheat in Iowa,** L. C. BURNETT (*Iowa Sta. Bul. 133, pp. 259-273, figs. 11*).—This bulletin reviews the history of winter wheat in Iowa, presents statistics showing the relative production of spring and winter wheat for the State, and reports the results of experiments carried on by the station. Notes are given on cultural methods and on crop rotations including winter wheat.

The average yields of 4 winter wheat and 4 spring wheat varieties at the station for the 5 years 1906-1910, inclusive, were 33.8 and 24.2 bu. per acre, respectively. Experiments with 10 varieties of winter wheat carried on from 1906-1910 showed that the Russian types Malakoff, Imported Turkestan, Minnesota No. 529, and Turkey Red gave uniformly good results and produced on an average for this 5-year period 36.9, 36, 35.5, and 34.3 bu. per acre, respectively.

A 4-year comparison of drilling and broadcasting winter wheat resulted in an average yield of 29.1 bu. per acre on the drilled and of 24.9 bu. on the broadcasted plats. It is stated that the best results at the station were secured from placing the seed in the top of the moist earth below the dust mulch, or about 1½ to 2 in. below the surface. The yields so far obtained have favored sowing early in September. In 1912, the station obtained a good stand and also broke the crust by drilling clover in the standing wheat about April 20.

**On the vitality of farm seeds,** W. CARRUTHERS (*Jour. Roy. Agr. Soc. England, 72 (1911), pp. 168-183, figs. 5*).—The author describes briefly a machine similar to, or identical with, the "Preparator" previously described by Hume and

Garver (E. S. R., 27, p. 235), and states that "a similar machine was made in England, at my suggestion, with the result that clover seeds may be purchased with a guaranteed germination of 98 or 100 per cent. This gain was clearly established by these experiments. . . ."

A brief account is given of a transfer of live wheat embryos to dead seed kernels of various colors. The results "clearly show that living embryos transferred to the food store of dead seeds utilize it freely, and that the store of food retains all its properties for many years after the seed is dead."

Samples of 43 kinds of farm seeds were secured from the harvest of 1895 and stored during the succeeding 16 years in paper bags in close cabinet drawers. Germination tests indicated that the germinating power of barley and wheat was but little affected during the first 5 years, but decreased with increasing rapidity from that time until the tenth year, when no live seeds remained. Oats showed no serious loss of vitality until after the ninth year. Five years later white oats showed no living seeds, but black oats germinated for 15 years. The retention of vitality by oats is attributed to the adherence of the glumes.

In case of grasses the "death of all the samples occurred between the eighth and thirteenth years." Three main types appeared, one represented by timothy and tall oat grass, in which vitality was well maintained for 4 years and dropped rapidly thereafter; a second, of which hard fescue and sheep fescue were most characteristic, in which the germination tests showed a rapid drop to a point below 10 per cent, at which they remained practically stationary for a year or so before vitality disappearing entirely; the third crop is typified by Italian rye grass and less perfectly by meadow fescue, and shows a fairly steady loss of vitality from first to last.

The 3 true clovers (red, white, and alsike) showed a slight loss of vitality during the first 3 or 4 years, a rapid loss of vitality for about 4 years more, and finally the gradual loss of the last 10 per cent during the next 3 or 4 years. Trefoil lost vitality very steadily from first to last. Sainfoin lost almost as steadily. Alfalfa decreased rapidly at first then changed little between the fifth and ninth years after which it decreased quite regularly, being practically dead at the end of the fourteenth year.

Of the cruciferous seeds tested, 5 sorts were entirely dead at the end of the thirteenth year, and 4, kale, white turnip, and purple and green top swedes showed very rapid decreases in vitality during the tenth year. The decrease in case of rape and the yellow turnip was decidedly slower but began somewhat earlier. Rape was entirely dead during the eleventh season. Carrots and yarrow seed lost their vitality at a rather uniform rate and entirely during the tenth and eleventh seasons, respectively. Tables and curves show in detail the results of the germination tests from which these conclusions are drawn, and tables state the results of other tests dealing with the rapidity of germination of seed of the same group of plants.

## HORTICULTURE.

[Report on investigations in plant heredity and plant shading], B. D. HALSTED ET AL. (*New Jersey Stas. Rpt. 1910, pp. 221-272, 277-282, 292-295, pls. 29, figs. 2*).—In continuation of previous investigations (E. S. R., 25, p. 444) inheritance in plants was studied in the following truck crops: Beans, corn, egg-plants, okra, peas, peppers, squashes, and tomatoes. In order to lay a foundation for the determination of rules of inheritance that may be of general application special emphasis has been laid upon the behavior of tomato crosses in their first generation. The types selected have been bred reciprocally with each other and the plants extensively studied from seedling to full maturity.

Results of this study to date are here briefly summarized. A full report of the work has been published in a series of bulletins (see page 742).

Owing to a prolonged drought poor results were secured from the corn breeding work in many instances. The behavior of a few of the more promising crosses is briefly discussed. A further study was made during the year relative to flintiness in sweet corn. The test appeared to point to two kinds of flintiness or starchiness, one of which, it is suggested, may illustrate a type of seed character that is transferred by the pollen; the other form is classed as an ear or plant character. When the latter form of flintiness is present it does not appear to be readily transmitted through cross pollination to adjacent pure sweet grains.

A number of eggplant crosses and hybrids are discussed with reference to their inherited characters, and attention is also given to the nature of the eggplant inflorescence and changes during the growth of the fruit. A similar but more detailed study of the life history and structure of the leading types of peppers is reported, together with tabular data on a number of second generation crosses.

In the work of breeding and selecting for choice sorts of tomatoes several promising crosses selected for length of the fruit have been tested. A few of these crosses are briefly discussed. A brief study similar to that for the eggplant was also made of the development of the okra fruit during the growing season. Tests of the pepino or melon pear (*Solanum muricatum*) indicate that it is of no economic importance as compared with the eggplant, its near relative.

Experiments in limitation of fruit bearing were conducted with tomatoes, eggplants, bush beans, and bush squashes. For the plants studied the results indicate that excessive fruit thinning unaccompanied by vegetative pruning leads to a rank vegetative growth and only a slight increase in the size of the few remaining fruits. There appears to be a certain limit for every plant as to the actual size of its fruits, regardless of the quantity produced.

Observations were made of the effect of a midsummer drought upon a number of ligneous plants. A well-marked zone of retardation in the growth of both leaves and stems corresponding to the drought period was observed. At the resumption of favorable moisture conditions, the leaves and stems again assumed normal size.

Tests of a number of ornamentals secured in previous breeding work are briefly noted. They include hybrid forms of dianthus, foxglove, *Nicotiana*, pansy, and hibiscus and a pelargonium cross. A comparative test of the Russian sunflower (*Helianthus annuus*) grown on poor soil and on rich soil resulted in an increased number of ray flowers for the heads growing on rich soil. A diagram is given showing the great variation in number of ray flowers in a large number of heads of the Blackeyed Susan (*Rudbeckia hirta*). Observations of leaf variation in the common ragweed (*Ambrosia artemisiifolia*), giant ragweed (*A. trifida*), green milkweed (*Acerates viridiflora*), and the Drooping Forsythia (*Forsythia suspensa*) are discussed and illustrated.

A preliminary experiment in growing plants under shade was conducted in the greenhouse during the summer of 1910 to serve as a guide for the selection of material and suitable conditions for a larger field experiment. Of the plants observed, it appears thus far that beans, *Bryophyllum*, radishes, *Kochia*, and corn furnish good examples of different effects of shade; but all except beans and *Bryophyllum* suffer too severely in the shade.

Inheritance studies with beans were continued along lines previously noted and are reported separately (pp. 277-281), by E. J. Owen.

**Horticultural information** (*Ohio Sta. Circ. 124, pp. 143-147*).—This circular comprises a guide to the accessible sources of information relative to various phases of horticultural practice. Attention is called to the publications of the state and government institutions and a list is given of books, bulletins, and periodicals dealing with horticultural subjects.

**Vegetable growing in Alabama**, P. F. WILLIAMS and H. M. CONOLLY (*Alabama Col. Sta. Circ. 14, pt. 2, pp. 59-83, figs. 2*).—Part 1 of this circular (E. S. R., 26, p. 740) discussed in detail commercial vegetable growing in Alabama. The present part contains popular directions for growing the more important vegetables in the home garden. Notes are given relative to storage, home canning, and some common insects and diseases of the garden.

A planting table adapted to Alabama conditions is appended.

**The  $F_1$  heredity of size, shape, and number in tomato fruits**, B. H. A. GROTH (*New Jersey Stat. Bul. 242, pp. 3-39, pls. 3, figs. 8*).—In continuation of a series of studies previously reported (E. S. R., 25, p. 828) this bulletin describes the inheritance, in the first generation of crosses, of macroscopical and microscopical structures in a number of types of tomatoes. Heredity of size and shape of fruit, number of locules in the fruit, size of the epidermis of fruit cells, and thickness of the radial wall of the epidermis in fruits are shown in a series of charts and discussed at length.

The principal deductions derived from the work are summarized as follows:

"Fruits of tomato types may possess latent factors for size and shape different from those they exhibit. Either the factors for the actual size and shape or the latent factors may be active in a cross to determine the size and shape of the  $F_1$  fruits.

"The size and shape of the  $F_1$  fruits are the geometric means between the size and shape corresponding to those factors of the parents, which were active in crossing.

"Fruits of tomato types may carry a factor for two locules; or a factor for two locules and another for addition cells; or a factor for two locules, another for addition cells, and a third for a broken center.

"When types possessing a factor for addition cells are crossed with two-celled types or with each other, the differences between the number of locules of the cross and those of the two parents separately bear to each other the same ratio as the differences between the surface area of the equatorial section of the  $F_1$  fruit and the respective areas of the two parents separately bear to each other.

"In crosses of types possessing factors for a broken center with other types, the inheritance of cell number in the  $F_1$  fruit is similar, except that another factor for cell number, a function of the respective factor for broken center, becomes active in determining the cell number of the cross.

"In the  $F_1$  fruits of types possessing factors for broken centers with each other, the factor for the lower cell number seems to be dominant. (Five instances only.)

"The  $F_1$  heredity of size, shape, and number in cell structures of the fruit skin is influenced by other unknown factors besides the factors for size, shape, and number apparent in the parents.

"Reciprocal and duplicate crosses usually agree in the inheritance of all characters studied; but they may differ greatly. Even fruits borne by plants raised from the seed of one fruit pollinated by pollen from a single flower may differ radically in characters of size, shape, and number.

"When crossing the rough 'Peaches' with smooth types, partial Xenia may occur."

Orchard irrigation studies in the Rogue River Valley, C. I. LEWIS, E. J. KRAUS, and R. W. REES (*Oregon Sta. Bul. 113, pp. 47, figs. 11*).—During the past 5 years the station has been conducting orchard irrigation investigations, especial attention being paid to a determination of the best dates as well as the best amounts and ways of applying the water under the various soil and orchard conditions found in the Rogue River Valley. The work for each season is here discussed in detail.

Irrigation practices in the Rogue River Valley were found to vary according to the soil, the kind of fruit grown, and the age of the trees. Some of the heavier soil types have shown best results under cultivation without the use of water. Soils of medium texture derived a direct benefit from light irrigation. The lighter types of soil under ordinary circumstances show that a considerable amount of irrigation is necessary for the production of commercial fruit on heavily bearing trees. The use of an excessive amount of cold water in the irrigation of pear trees on sticky soils is considered a questionable practice, since it did not increase the size or quality of the fruit and the result on the tree was detrimental rather than beneficial. Bartlett pear trees which are in good vigor and planted on strong soils appear to become more susceptible to disease under irrigation.

Irrigation aided in giving a larger percentage of fruit of marketable size. In some cases the reduction in the number of windfalls amounted to as high as 15 per cent of the crop. There were less culls caused by calyx cracking on the irrigated plats than on the dry checks. Irrigation had a tendency to keep both the wood and foliage more active in the fall, as well as to prevent premature ripening of the fruit. The shape of the fruit was found to be materially changed by irrigation. The apples receiving the best care were more elongated and angular, while those that suffered through lack of moisture had a tendency to become flat. The effect on color was more noticeable on the lighter soils where red apples were grown. The irrigated apples had a brighter, more attractive color while those grown on the checks were duller yet deeper in color. In many cases irrigated trees had more numerous and stronger fruit buds for the succeeding crop. By means of irrigation a much better stand of cover crop can be secured in late summer and early fall. Attention is called to the importance of cultivation and good drainage as adjuncts to irrigation.

The temperature of well water was found to increase in some cases as much as  $8\frac{1}{2}^{\circ}$  during the day while flowing in open furrows to the point of distribution. Water used from an irrigation ditch showed in some cases an increase of  $15\frac{1}{2}^{\circ}$  over the morning temperature. In both cases where temperatures were read it was found that the soil had decreased in temperature immediately following the irrigation. The decrease was more noticeable in the surface soil. It amounted in some instances to a difference of  $3^{\circ}$  in temperature.

To assist in determining the benefit or detriment of irrigation with respect to the development of the fruit itself, a study of the effect of irrigation on the chemical composition of the apple is now in progress.

Cover crops for Michigan orchards and vineyards, H. J. EUSTACE (*Michigan Sta. Circ. 18, pp. 123-134, figs. 10*).—This circular describes the most common systems of orchard soil management, and discusses the value of various plants for cover crop purposes as determined in orchards of various ages and on different soil types and located in various parts of the State.

Of the leguminous crops winter vetch and Mammoth clover appeared to be the most valuable, the latter doing somewhat better than winter vetch upon a clay soil. Spring vetch and Canada peas have also proven of value. Of the nonleguminous crops buckwheat, rye, oats, and barley were found to be adapted

to Michigan conditions. A combination of oats and winter vetch or oats and peas is considered much better than oats used alone.

**The pollination question** (*Oregon Sta. Circ. 20, pp. 7*).—A discussion of the pollination of apples and pears, in which is set forth some of the practical results obtained in the station's work throughout the State for several years past. A general broad view is also given of the important points to be kept in mind with respect to orchard pollination. A publication dealing exclusively with the research phases of the pollination work will appear in the future.

The circular concludes with a list of commercial varieties of apples and pears most grown at the present time in Oregon and grouped according to the desirability of interplanting to secure best results from pollination.

**Top working apple trees.** C. P. HALLIGAN (*Michigan Sta. Circ. 14, pp. 92-94, figs. 2*).—A popular circular describing the method of top working apple trees by means of the cleft graft.

**Dressings for pruning wounds of trees.** A. D. SELBY (*Ohio Sta. Circ. 126, pp. 163-170*).—A popular circular containing suggestions relative to available antiseptic materials, the essential requirements of a wound dressing, and the available materials for wound dressings.

**Recent investigations in fig culture and caprification.** G. P. RIXFORD (*Pacific Rural Press, 84 (1912), Nos. 2, pp. 28-30; 3, pp. 52-53*).—A popular review of the progress made in recent investigations dealing with the establishment of the Smyrna fig industry in California.

The severe frosts of the past winter proved very disastrous to the mamme crop of caprifigs in which the *Blastophaga* are harbored during the winter. To offset this difficulty a California fig grower made the important discovery that the mamme figs may be taken from the tree in December before the advent of heavy frosts, stratified in a box of clean, damp sand, and stored over winter in a cellar without injuring the *Blastophaga*, which were found to come out as usual and enter the profichi, or spring crop of caprifigs. By harboring the insects in this manner it is suggested that it may be possible to extend the Smyrna fig industry all along the Gulf region of the Southern States from Florida to Texas.

**New method of extracting olive oil.** F. T. BIOLETTI (*Pacific Rural Press, 84 (1912), No. 16, p. 372*).—A new method of extracting olive oil from fresh olive pulp, which has been recently tested in Italy with good results, is here briefly described.

Instead of using a press as in the ordinary methods of extracting olive oil, the extractor consists of 2 concentric cylinders separated by a narrow space. The outer cylinder is of sheet metal and the inner one is a metallic screen. The olive pulp is placed in the inner cylinder and kept in motion by a revolving axle furnished with aluminum pallets. By means of a suction fan attached to the lower half of the outer cylinder a slight difference of pressure is produced between the inside and the outside of the inner cylinder. The oil and water are thus extracted from the pulp. Contrary to the results secured in the ordinary press, the oil comes out more easily than the water and a greater proportion of water remains in the pulp. It is claimed that about 10 per cent more oil is obtained from the new system and that the quality of the oil is uniform and equal to or better than the first run from ordinary presses. The olives can be worked while fresh and the troubles and defects due to drying, molding, and rotting are avoided.

**Report on experiments with citrus fruits at the Beeville substation.** A. T. POTTS (*Texas Sta. Bul. 148, pp. 5-22, pl. 1, figs. 10*).—This bulletin comprises a brief résumé of the experiments with citrus fruits which have been conducted at the substation during the past few years. The varieties which

have proved most resistant to cold are indicated and attention is called to the most improved methods of cultivation to secure both production of fruit and resistance to cold.

The experiments to date have shown that the only varieties which are sufficiently frost resistant to be used in commercial plantings are the Kumquat and the Satsuma. By selecting favorable sites, planting windbreaks, giving good cultivation, and sowing winter cover crops, the danger from frost injury can be greatly reduced. It is recommended, however, that no extensive planting be made without some well-defined plan for fighting the frost.

Experiments in the use of orchard heaters during the winters of 1911 and 1912 are described. The author concludes in substance that although there is no question as to the value of orchard heaters as an aid in frost protection, since the freezes that occurred in the winters of 1911 and 1912 would tax to the utmost any system of orchard protection, it is yet to be determined whether orchard heaters may be used for a number of years under Texas conditions with a degree of profit to the grower. Shortly before cold weather is expected all varieties of citrus fruits should have clean earth piled above them to a height of 12 to 18 in. In case of a severe freeze all wood thus covered will be saved.

**The better oranges, limes, and lemons.** E. CHAVEZ (*Estac. Agr. Cent. [Mexico] Bol.* 67, 1912, pp. 72, pls. 42).—This comprises descriptive accounts of the principal species and varieties of citrus.

## FORESTRY.

**The Michigan woodlot.** J. F. BAKER (*Michigan Sta. Circ.* 17, pp. 107-122, figs. 6).—This is a brief popular treatise on woodlot management. It discusses the scope of farm forestry, the present condition of Michigan woodlots, timber estimating, woodlot protection, cutting, reproduction, establishment of new woods, and species and soils. A short note is also given relative to the State cooperative woodlot work.

**Forty years' management of woods.** D. TAIT (*Quart. Jour. Forestry*, 6 (1912), No. 4, pp. 279-298).—This comprises a report of the management of the woods on the Owston Park estate, near Doncaster, England, for a 40-year period with special reference to the financial returns secured.

**The relative yields obtained by the destructive distillation of different forms and species of hardwoods.** L. F. HAWLEY and R. C. PALMER (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York]*, 6 (1912), Sect. IV, pp. 138-146).—Tests made to determine the commercial value of different species of hardwoods as raw material for distillation are described. Data obtained in each of the distillations, together with the average yields of alcohol and acid from different parts of the tree, are given for beech, birch, maple, gum, chestnut, and hickory.

**Distillation of resinous wood by saturated steam.** L. F. HAWLEY and R. C. PALMER (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York]*, 13 (1912), Sect. VIa, pp. 151-176, figs. 5).—This is a report of an investigation of the fundamentals of the steam distillation process. Pitchy longleaf pine was used in the distillation tests. The results are presented in tabular form and discussed. Consideration is given to the effects of the size of chip, pressure of steam, speed of distillation, and end point at which distillation is stopped, on the yield of total oil, the composition of the oil, and the amount of steam required to remove the oil.

Tests to determine the commercial value of wood preservatives. A progress report, H. F. WEISS (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 13 (1912), Sect. VIa, pp. 279-300, figs. 5*).—An account of preliminary experiments conducted to determine the practical value of a number of substances which have been either used or suggested as wood preservatives. The following points were studied in these tests: The important chemical and physical properties of the preservative; the effect of the preservative on the strength of the wood treated; penetration and diffusion of the preservative through the wood; permanency of the preservative after its injection into the wood; the combustibility of the treated wood; toxic efficiency of the preservative; the corrosive action on steel; and the effect of the preservative on paint applied to the wood subsequent to treatment.

Recent investigations in the realm of wood conservation. E. F. PETRITSCH (*Centbl. Gesam. Forstw., 38 (1912), Nos. 6, pp. 265-282, figs. 8; 7, pp. 321-333, figs. 3; 8-9, pp. 383-392, figs. 2*).—A general review of experimental work in the use of wood preservatives.

### DISEASES OF PLANTS.

Smut fungi and smut diseases, V. O. BREFELD (*Untersuch. Gesamttgeb. Mykol., 1912, XV, pp. V+151, pls. 7*).—In continuation of previous studies of the author (E. S. R., 18, p. 449), this volume is largely taken up with a consideration of smut fungi. The pathological effect of the fungus on the host plant; the preservation of the fungi within and without the host plants; a study of some of the fungi related to smuts, such as *Geminella*, *Entorrhiza*, and *Ustilago*idea; the present state of knowledge regarding the smut diseases; hemibasidia forms; and fruiting forms of smut fungi are discussed. Chapters are also given on the occurrence of chlamydozoospores and comparisons of their form in the higher and lower fungi.

Two new species of rusts, W. H. LONG (*Mycologia, 4 (1912), No. 5, pp. 282-284*).—A description is given of two parasitic fungi, one which is the type of a new genus, *Tricella acuminata* n. sp., occurring on *Coursetia glandulosa*, and the other, *Peridermium inconspicuum* n. sp., which was collected on *Pinus virginiana*.

The present state of knowledge regarding the propagation of rust, J. BEAUVÉRIE (*Ann. Soc. Bot. Lyon, 36 (1911), pp. 24-60*).—This is a critical review of literature prior to 1911 and a discussion of the present state of information regarding parasitism, specialization of rusts, immunity from their attacks, and the various theories regarding the propagation and wintering of rusts. A bibliography is appended.

Studies on *Corticium javanicum*, A. RANT (*Bul. Jard. Bot. Buitenzorg, 2. ser., 1912, No. 4, pp. 50, pls. 9*).—This parasite is here listed as now known on 141 species contained in 104 genera. Culture methods are here detailed and a bibliography is given. See also a previous note (E. S. R., 25, p. 546).

The aecidia of *Puccinia fusca*, A. F. PAVOLINI (*Bul. Soc. Bot. Ital., 1912, No. 4, pp. 90-93*).—This is a very brief discussion of the development of the aecidiospores in the case of this fungus, suggesting a further study thereof and comparative studies of other Uredineae in this respect.

Fungus diseases, J. E. HOWITT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 37 (1911), pp. 47-51, figs. 3*).—Notes are given on the occurrence of a considerable number of plant diseases, some of which are said to be becoming prevalent and destructive in Ontario. In addition directions are given for treatment to prevent attacks of loose smut of wheat (*Ustilago tritici*), crown rust of oats (*Puccinia coronata*), hollyhock rust (*P. malvacearum*), rose leaf

blotch (*Actinonema roseæ*), blight of ginseng (*Alternaria panax*), and sooty blotch of apples (*Leptothyrium pomi*).

**Phytopathologic notes,** G. ARNAUD (*Ann. École Nat. Agr. Montpellier, n. ser., 12 (1912), No. 1, pp. 5-22, figs. 9*).—The author gives the results of studies on several parasitic fungi substantially as follows:

*Spheropsis pseudo-diplodia*, a very variable fungus occurring on many woody plants, is considered to include properly several forms known by other names as species of *Spheropsis*, *Macrophoma*, *Diplodia*, etc. *Physalospora cydonia* is thought to be the perfect form of *S. pseudo-diplodia*. The latter is a weak parasite, attacking usually plants or parts already injured or weakened from other causes, increasing the injury, and hastening death, or else only forming cankers in case of resistant plants. The fungus is often found in relation with the work of a bark-boring beetle (*Scolytus*).

*Phoma (Fusicoccum) cinereascens*, the pycnidial stage of *Diaporthe cinereascens*, is said to be the only vegetal parasite seriously affecting *Ficus carica*, causing on twigs, branches, and trunk extensive cankers which slowly destroy the tree, the annual loss therefrom being important. The progress of this parasite is found to be closely related to the inroads of a minute beetle, *Hippoborus ficus*.

*Glœosporium verrisequum*, said to be the pycnidial form of *Guomonia veneta*, causing anthracnose of the plane tree, produces in spring alterations along the veins of the leaf and in autumn along the borders, causing yellowing of the leaves and drying of the branches affected.

**Plant pathology,** P. J. BUTLER (*Ann. Rpt. Bd. Sci. Advice India, 1910-11, pp. 112-117*).—Notes are given on several diseases of the palm, soft rot of ginger (ascribed to *Pythium gracile*), a leaf disease of turmeric (said to be due to a species of *Taphrina*), a parasitic disease of the tea bush and one of tea seed, some forest tree diseases, fruit diseases, etc. A brief bibliography is appended.

**Contributions to the study of straw blight of cereals,** G. FROX (*Ann. Sci. Agron., 4. ser., 1 (1912), I. No. 1, pp. 3-29, figs. 3; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 4, pp. 1054-1056*).—Black foot or straw blight, which has been attributed to *Ophiobolus graminis* and *Leptosphaeria herpotrichoides*, is held by the author, as the result of his studies, to be due to the latter organism. This fungus appears in May or early in June, spreading rapidly and showing as a felt-like mass on the stalks, which turn gray and finally wither. The mycelium penetrates the cells, preferring those near the vascular bundles. The black perithecia appear inside the leaf sheaths about September, and in November and December contain a large number of spores which escape in cold, dry weather and easily infect the young wheat plants. Infection of older plants is rare and difficult. The mycelium lives through the winter and in the next fall produces a still larger number of perithecia.

The incubation period is long. The spores retain their power to germinate while in the perithecia, but on escaping soon germinate or perish as they lose their vitality quickly in light (especially sunlight) and in dry air, these conditions also retarding mycelial growth. The spores were found much more resistant to iron sulphate than to the corresponding copper salt.

The author thinks that the conidia attributed to a supposedly new fungus found in May, 1909, and provisionally named *Cercosporiella herpotrichoides*, are the summer fructifications of *L. herpotrichoides*. The fungus requires an alkaline or a neutral medium for its development, growth being checked by very slight acidity.

Means suggested for control of this fungus include (1) late sowing (January or February); (2) selection of resistant varieties; (3) thin sowing, permitting access of light and dry air; and (4), in case of planting in drills, unequal widths between rows (narrow and wide spaces alternating).

Foot rot of grains, R. DE POLO and E. VOGLINO (*Coltivatore*, 58 (1912), No. 18, pp. 567-572, figs. 2).—The authors briefly state the results of their observations on this disease, which is said to have assumed importance in parts of Italy.

It was noted that the plants and varieties which are most forward, luxuriant, and promising in spring suffered more from the disease than did those of slower and more open growth, later maturity, and smaller yield. A series of experiments extending over several years is suggested in order to find a means of avoiding the loss which is said now to be large.

The black foot disease of wheat, L. MANGIN (*Jour. Agr. Prat.*, n. ser., 24 (1912), No. 32, pp. 174-176, figs. 3).—Under the above name the author describes a disease of wheat in which the bases of the culms are attacked. It causes a reduction in the mechanical tissues of the plant to such an extent that the wheat lodges irregularly, without reference to winds or rain. Two fungi are held to be responsible for this trouble, *Ophiobolus graminis* and *Leptosphaeria herpotrichoides*, the latter species being considered the more important in causing its development.

For the control of this disease the author recommends clearing the soil of the fungus by burning the straw, which is of little value when attacked by the fungus, treating the seed with a solution of copper and dusting with lime, fertilizing the land with superphosphate at the rate of 1,500 kg. per hectare, the use of sulphate of iron on the soil before seeding, late seeding, and a consistent system of rotation of crops.

A fungus affecting pastures in Manning River district, G. MARKS (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 8, p. 682).—A brief account is given of an attack of *Phyasarum cinereum* on grasses and clovers of all classes except Paspalum. It destroys plants in small circular patches, ranging in diameter from a few inches to a foot or more. As its destruction is desirable it is suggested that the infected areas be covered and burned.

Potato disease, F. BASTY (*Petite Rev. Agr. et Hort.*, 18 (1912), No. 421, p. 135).—The author calls attention to the high price of potatoes due to a number of causes, among them attacks of *Phytophthora infestans*, and for its control he recommends spraying with a copper sulphate solution or with Bordeaux mixture. Two treatments are believed to be sufficient in an ordinary year, one to be made before the appearance of any disease, the other to follow after an interval of 2 weeks or more.

The effect of certain chemical substances on the vitality of the buds of potato tubers, and their disinfective action on potato blight (*Phytophthora infestans*), F. STOWARD (*Proc. Roy. Soc. Victoria*, n. ser., 24 (1911), No. 2, pp. 270-292, pls. 4).—The principal object of this investigation was to ascertain the influence, under definite conditions of time, temperature, and concentration, of certain antiseptic compounds in solution on blight-free or blight-infected tubers, particularly in regard to the annihilation of the buds of the treated tuber, and in case of blight-infected material, of the hibernating mycelium of *P. infestans*. The tubers were subjected to solutions of common salt, sulphuric acid, boric acid, carbolic acid, and formalin.

When the tubers were intact, blight free, and mature the entry of the solute during the earlier stages of immersion was chiefly if not solely by way of the buds. These were destroyed by soaking the potatoes for 10 hours in a 10 per cent solution of sulphuric acid. This was also found to destroy all the mycelium

in blight-infested tubers, entering in this case not only through the buds but through those parts of the skin which had been damaged by the fungus.

The results of the investigation indicated that the storage and cooking qualities of the tubers were not injuriously affected by the treatment.

**Investigations on the root disease of sugar cane.** J. R. JOHNSTON (*Porto Rico Prog.*, 3 (1912), No. 10, pp. 11, 15).—As a result of examinations of canes diseased near the root, the author thinks that there are in Porto Rico various types of root disease, only one of which, *Marasmius sacchari*, has been well worked out. Some other forms found on diseased roots are *Clathrus* sp., *Asterostroma albidocaracum*, and perhaps, *Corticium* sp., some of which may be important factors in the production of this condition.

**Report of committee on root gall to the American Association of Nurserymen.** E. A. SMITH (*Nat. Nurseryman*, 20 (1912), No. 8, pp. 300, 301).—A preliminary report is given of cooperative experiments that have been established by a committee of the American Association of Nurserymen, the work having been undertaken during 1911. The experiments, some of which are in cooperation with experiment stations, are now in progress in 10 different States, the object being to determine the cause and method of control of the different forms of root gall on nursery stock.

**Apple blister canker and methods of treatment.** W. O. GLOYER (*Ohio Sta. Circ.* 125, pp. 149-161, figs. 7).—The author describes the blister canker of apples due to the fungus *Nummularia discreta*, which is said to be quite prevalent in southern and eastern portions of Ohio. The fungus is said to be a wound parasite, and is difficult to control when once it has attacked a tree. Except in cases of slight attack the tree ultimately succumbs to the disease.

To prevent infection from the blister canker fungus the author recommends that precautions be taken to prevent the drying of the tissues following pruning or other injury. This may be done by covering the wounds with a suitable dressing, such as asphaltum, grafting wax, etc. Proper orchard sanitation, such as removal and destruction of diseased parts, is also recommended.

**Bitter pit in apples.** A. J. EWART (*Proc. Roy. Soc. Victoria, n. ser.*, 24 (1911), No. 2, pp. 367-419).—The author conducted a series of experiments to test the theory of Miss White (*E. S. R.*, 26, p. 55) that bitter pit of apples is due to local poisoning. In his experiments a large number of inorganic, organic, and gaseous poisons were tested on the pulp of apples under varying conditions.

It was found that the ripe pulp cells of apples are more sensitive to various poisons than any other known organisms, the limit of toxic action in the case of mercuric chlorid being with a concentration of 1 to 10,000,000,000. The cuticle and bloom of sound apples were found remarkably impermeable to poisons, but when these were removed the poison penetrated readily. Young apples were found more easily penetrated by dissolved poisons than old ones, but their pulp cells were more resistant. Hence a young apple may absorb sufficient poison to kill a portion of its tissue when more mature, without any immediate toxic effect being shown.

Substances occurring normally in the soil, it is stated, may exercise a toxic effect on the fruit when presented singly, but in mixtures their individual poisonous action is decreased. The poisonous action of copper sulphate and other soluble metallic substances may be decreased by the addition of substances which decrease the percentage of free ions, and in this way it is possible to modify Bordeaux mixture and arsenate of lead without appreciably affecting their value as insecticides and fungicides. Zinc arsenite was found less poisonous than lead arsenate and is considered equally effective as an insect poison. Among the gases present in the air, ozone, ammonia, and nitric acid were found able to produce surface pitting in apples, but only in amounts and

with lengths of exposure much greater than those presented under ordinary conditions.

In conclusion the author states that he considers it established that bitter pit is, strictly speaking, not a disease but a symptom of local poisoning produced in the sensitive pulp cells of the apple, that more than one poison may produce it, and that the poisons may be derived from more than one source.

A new leaf spot fungus on pear trees in Pavia, L. MONTEMARTINI (*Riv. Patol. Veg.*, 5 (1912), No. 14, pp. 225, 226).—A brief report is made on the discovery by the author of a fungus causing a leaf spot disease of pears in Pavia. The fungus is described under the name *Hadrothricum piri* n. sp.

Grape mildew and the time necessary for infection, L. RAVAZ and G. VERGE (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 7, pp. 195, 196; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases*, 3 (1912), No. 4, p. 1958).—It is claimed to have been shown by these experiments that 1½ hours is sufficient time for infection to occur by fresh conidia of *Plasmopara viticola* in water on the lower side of the leaf.

Treatment of chlorosis of grape, J. VERCIER (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 23, pp. 713, 714).—This is a very brief account of some tentative experiments in treating chlorosis of the grape with sulphate of iron. The results were encouraging and further trials are promised.

Roncet and arricciamento, E. PANTANELLI (*Coltivatore*, 58 (1912), No. 13, pp. 399-405, figs. 6).—This continues the author's previous discussion of roncet (*E. S. R.*, 25, p. 654; 26, p. 851), now noting more particularly its possible connection with another affection of the grape, occurring sporadically in Italy and known as frizzle disease. Some relations of these two abnormalities to hybridization of certain forms and to root pressure and transpiration are also noted. A later report is promised.

The spread of American gooseberry mildew in Baden, K. MÜLLER (*Ztschr. Pflanzenkrankh.*, 21 (1911), No. 8, pp. 449-454, fig. 1; *abs. in Riv. Patol. Veg.*, 5 (1912), No. 14, pp. 227, 228).—A discussion is given of the first appearance in 1908 of *Sphaerotheca mors-uvæ* and of its later appearances in parts of Baden. It is claimed that all outbreaks originated where stock brought from other sections had been planted and that the spread from wind-borne conidia in summer is of only local importance.

Stem-end rot and gummosis, H. S. FAWCETT (*Proc. Fla. State Hort. Soc.*, 24 (1911), pp. 51-52, pl. 1).—A summary account is given of the investigations carried on by the author while at the Florida Station on stem-end rot, due to Phomopsis, and gummosis, caused by *Diplodia natalensis*, previous notes upon them having been given elsewhere (*E. S. R.*, 25, p. 450; 26, p. 449).

Some fruit diseases, J. B. RORER (*Dept. Agr. Trinidad and Tobago Bul.*, 11 (1912), No. 70, pp. 75, 76).—Descriptions are given of anthracnose of the mango due to *Glaucosporium mangifera* and anthracnose of the avocado caused by *Colletotrichum* sp. It is said that both of these diseases can be controlled by spraying with Bordeaux mixture if the work be thoroughly done and started in good season.

Banana diseases are briefly described, the two most prevalent troubles being the Panama and moko diseases. The Panama disease is believed to be due to a species of *Fusarium*, while the moko disease is apparently of bacterial origin. It is stated that the varieties of banana subject to one disease are apparently quite resistant to the other.

Spraying cacao, J. B. RORER (*West Indian Bul.*, 12 (1912), No. 3, pp. 275-277; *Dept. Agr. Trinidad and Tobago Bul.*, 11 (1912), No. 70, pp. 34-36).—In order to ascertain whether cacao diseases, and particularly the causer and black pod rot, due to *Phytophthora faberi*, can be controlled by spraying, the

author conducted a series of experiments on a block of 1,000 trees divided into two equal parts, one of which was sprayed with Bordeaux mixture while the other was left unsprayed.

At harvest all fruits were carefully examined and the results show conclusively that spraying cacao is an efficient method for controlling the diseases. Allowing for labor, materials, etc., a gain of over \$20 from 500 trees was reported in a single season.

**Cacao canker**, E. ESSLD (*West Indian Bul.*, 12 (1912), No. 3, pp. 302-308).—The results of a six months' study of cacao canker in Surinam have led the author to the belief that the disease is not primarily due to *Phytophthora*, as has been claimed by Rorer (E. S. R., 23, p. 748), but is to be attributed to attacks of *Spicaria colorans*, as previously described by A. E. van Hall de Jonge (E. S. R., 22, p. 547).

A possible inference to be drawn from the studies on cacao canker, A. FREDRIOLM (*West Indian Bul.*, 12 (1912), No. 3, pp. 308-310; *Dept. Agr. Trinidad and Tobago Bul.*, 11 (1912), No. 70, pp. 46-48).—The author is disposed to criticize the claim of Rorer (E. S. R., 23, p. 748) that pod rot, canker, and chupon wilt of cacao is solely due to *Phytophthora* sp. He considers canker as a condition and not a specific disease and that several parasitic fungi attacking cacao trees may produce cankerous conditions.

**Fungus diseases of cacao**, F. W. SOUTH (*West Indian Bul.*, 12 (1912), No. 3, pp. 277-302).—Popular descriptions are given of the principal diseases of cacao known to occur in the West Indies and contiguous regions. A bibliography of references is given.

**Bud rot of the coconut palm**, J. B. RORER (*Dept. Agr. Trinidad and Tobago Bul.*, 11 (1912), No. 70, pp. 68, 69).—The disease of the coconut palm attributed by Johnston (E. S. R., 26, p. 649) to *Bacillus coli* is described. This disease appears to be quite prevalent in Trinidad, and sanitary measures have been taken to prevent its spread, about 18,000 trees having been destroyed. Since this work has been done there has been a marked reduction in new cases of infection, and the author claims that this indicates rather conclusively that the disease can be held in check by these measures, provided they are widely enforced.

**Rows of spots on the leaves of palmyra palms**, W. McRAE (*Agr. Jour. India*, 7 (1912), No. 3, pp. 272-279, pls. 5).—The author describes a form of disease in the leaves of palmyra palm that is due to the fungus *Pythium palmivorum*, the cause of the bud rot of this tree.

The parts of this palm most susceptible to attack are the succulent yellow parts of the leaf sheaths. When the fungus begins its attack, well above the level of the growing point, it eats its way inward through the leaf sheaths until it reaches the young expanding leaves. The tissues of the leaves are then attacked, the fungus boring holes through them which become quite evident upon the expansion of the leaves.

Cutting out the affected leaves is recommended as probably the most satisfactory method of dealing with this trouble.

**A preliminary note on the heredity of fungus diseases of certain plants**, L. BLARINGHEM (*Bul. Soc. Bot. France*, 59 (1912), No. 2-3, pp. 217-220).—A record is given of observations on *Lolium temulentum*, which is often attacked by a fungus; *Althæa rosea*, the seeds of which are commonly infected with *Puccinia malvaccarum*; and *Oenothera nanella*, which is claimed to be a dwarf form of *Æ. lamurckiana*, attacked by a Micrococcus. From the frequency of the occurrence of these diseases on their host plants, the author thinks the relation of symbiosis has become an acquired character.

**The case of *Lolium temulentum* and *Althæa rosea***, S. BUCHET (*Bul. Soc. Bot. France*, 59 (1912), No. 2-3, pp. 188-191).—The author discusses the sup-

posed dependence of *L. tumulatum* and *A. rosea* on the symbiotic fungi which commonly infest them. He claims that they may and do exist absolutely independently of their fungus symbionts without changing their character in any degree. He holds that the necessary dependence of the host on the fungus does not exist.

**Stem rot of carnations**, M. A. BLAKE and A. J. FARLEY (*New Jersey Stat. Rpt. 1910*, pp. 78-81).—Severe losses due to stem rot of carnations have been reported by florists in several parts of the State. It has been found that the disease is especially severe upon plants that are bruised or injured in cultivation or during the process of benching. The stations have carried on experiments to determine means by which the losses can be reduced, and red shale soil has been studied with a view to its adaptability for the growing of carnations. The results of a test of this soil mixed with different proportions of sand and with and without composted manure are described.

The results indicate that the addition of composted manure to soils of the red shale type intended for the forcing of carnations increases the danger of loss by stem rot, also that the addition of considerable sand with the composted manure further increases the danger of loss. The stations have succeeded in growing carnations successfully upon red shale soil without the use of composted manure, and if proper physical conditions of the soil can be secured and chemical fertilizers used, it is believed that there will be little danger of loss from fungus diseases.

**Foot rot of carnations**, L. FONDARD (*Petite Rev. Agr. et Hort.*, 18 (1912), Nos. 416, pp. 80, 81; 418, p. 103; 420, p. 128).—This is a brief synthetic discussion based on investigations conducted mainly by others.

This disease, known also as root disease, branch disease, etc., and found mainly in the coastal region of France, though also occurring in other parts, is ascribed to a fungus, *Fusarium dianthi*, which may manifest itself in and near the roots or in other and all parts of the plant. It is said to be perpetuated either by mycelium carried in the cuttings and developing with these, or by spores, some of which are thought to live for one or more years on debris and roots in soil and to be carried to sound plants by the operations of cultivation, by manures, and especially by irrigation with a strong dashing stream of water.

As preventive measures, the most critical examination of cuttings is recommended, also rotation of plants so as to give time for all spores to die in the soil.

**A disease of the leaves of the garden geranium**, ALI RIZA (*Bul. Trimest. Soc. Mycol. France*, 28 (1912), No. 2, pp. 148-150, figs. 2).—The author describes a disease of the leaves of the garden geranium (*Pelargonium peltatum*) which is attributed to *Coniothyrium trabuti* n. sp. A technical description of the fungus is given.

**An anomaly of *Pelargonium capitatum***, P. BACCARINI (*Bul. Soc. Bot. Ital.*, 1912, No. 4, pp. 67-74, fig. 1).—The author gives a description of certain excrescences observed on this plant and an account of his studies as to their origin and real nature. Regarding these, however, he offers as yet no very decided opinions.

**Polystictus versicolor as a wound parasite of catalpa**, N. E. STEVENS (*Mycologia*, 4 (1912), No. 5, pp. 263-270, pls. 2).—During 1911-12 the author has investigated the wood rots of catalpa in Kansas, particularly with reference to second growth stands.

It has been found that the most serious wood rot of living catalpa is caused by *P. versicolor* and that coppice shoots on partly decayed stumps are less

readily infected than are branches of a partly decayed trunk. In examining the diseased material tyloses were found abundant in the outer wood, and there is apparently a constant relation between the presence of the decayed area in the trunk and their formation. In addition to the above species, the author frequently found fruiting bodies of *Trametes sepium* on catalpa stumps.

**Diseases of the chestnut and other trees,** H. METCALF (*Trans. Mass. Hort. Soc., 1912, pt. 1, pp. 69-95*).—This is an address presented before the Massachusetts Horticultural Society in which an outline account is given of various forest tree diseases, particular attention being paid to the chestnut bark disease (*Diaporthe parasitica*). The relation of the disease to the condition of the tree is discussed, and outlines are given of methods for control, together with the proposed program for combating the disease and preventing its spread.

A bibliography is appended.

**Oak Oidium in France,** G. TRINCHIERI (*Bul. Soc. Bot. Ital., 1912, No. 4, pp. 100-102; Jour. Agr. Prat., n. ser., 23 (1912), No. 13, pp. 402, 403*).—This is a brief discussion of the contribution on this subject made by Arnaud and Foëx (E. S. R., 26, p. 551). The present author holds that a more complete comparison and experimental data are necessary before the oak Oidium of Europe can be safely considered as identified with the American species, *Microsphaera quercina*.

**Uredo manihotis injurious to Manihot glaziovii in Brazil,** E. ULE (*Tropenpflanze, 16 (1912), No. 2, pp. 91-95; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 4, p. 1065*).—The author reports that this fungus was found by him to attack rubber trees in the State of Ceará and neighboring regions, causing rust-colored spots on the leaves and large excrecences and witches' brooms on twigs and branches, reducing the yield of rubber, killing the branches, and eventually destroying the trees affected.

Careful pruning out and burning all diseased parts is said to be the only remedy yet found effective.

**Prevention of mold,** G. G. HEDGCOCK (*Chicago [1912], folio*).—This paper, which was read before the National Slack Cooperage Manufacturers' Association, St. Louis, Mo., May, 1911, gives a brief report on 10 experiments running from 1905 to 1910.

It was found that for the treatment of lumber sodium bicarbonate at a strength of 5 to 8 per cent is, on the whole, the most economical and satisfactory. Some other compounds, notably potash alum and corrosive sublimate, either have not been fully proved or are too dangerous to be unqualifiedly recommended. Kiln drying is stated to be the best preventive of stain due to mold.

**The spreading qualities of spraying mixtures,** J. WEINMANN (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 33 (1912), No. 23, pp. 709-712*).—This is an account of a series of experiments on the wetting capacity of Bordeaux and Burgundy mixtures with addition of various substances to lower the surface tension and permit greater spreading on the surface treated therewith.

It was found that for the purpose in view ordinary white soap was as effective as a specially prepared soap sold in the form of powder. Polysulphids without soap do not augment the wetting capacity of the mixture, but the two together added to neutral or alkaline Burgundy mixture give excellent results. Sapindus alone was found to give results almost equal to soap alone but inferior to a mixture of the two.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

Dictionary of biology, H. SCHMIDT (*Wörterbuch der Biologie. Leipzig, 1912, pp. VIII+581*).—An illustrated biological dictionary.

Mice: Their breeding and rearing for scientific purposes, J. F. DANIEL (*Amer. Nat., 46 (1912), No. 559, pp. 591-604, figs. 4*).—The author describes an intensive method by which he has been able to rear mice in abundance.

The rat and its relation to public health (*Washington: Pub. Health and Mar. Hosp. Serv. U. S., 1910, pp. 254, pls. 9, figs. 59*).—The subject is here dealt with by a number of authors, as follows: Natural History of the Rat, by D. E. Lantz (pp. 15-27); Plague Infection in Rats, by G. W. McCoy (pp. 29-48); Rat Leprosy, by W. R. Brinckerhoff (pp. 49-53); Bacterial Diseases of the Rat, other than Plague and Rat Leprosy, by D. H. Currie (pp. 55-57); Organic Diseases of the Rat, including Tumors, by G. W. McCoy (pp. 59-68); The Ectoparasites of the Rat, by N. Banks (pp. 69-85); The Internal Parasites of Rats and Mice in Their Relation to Diseases of Man, by C. W. Stiles and C. G. Crane (pp. 87-110); Compendium of Animal Parasites Reported for Rats and Mice, by C. W. Stiles and A. Hassall (pp. 111-122); The Flea and Its Relation to Plague, by C. Fox (pp. 123-144); Rodents in Relation to the Transmission of Bubonic Plague, by R. Blue (pp. 145-152); Rodent Extermination, by W. C. Rucker (pp. 153-162); Natural Enemies of the Rat, by D. E. Lantz (pp. 163-169); Rat Proofing as an Anti-plague Measure, by R. H. Creel (pp. 171-178); The Inefficiency of Bacterial Viruses in the Extermination of Rats, by M. J. Rosenau (pp. 179-204); Plague Eradication in Cities by Sectional Extermination of Rats and General Rat Proofing, by V. G. Heiser (pp. 205, 206); The Rat in Relation to Shipping, by W. C. Hobdy (pp. 207-213); The Rat as an Economic Factor, by D. E. Lantz (pp. 215-226); and The Rat in Relation to International Sanitation, by J. W. Kerr (pp. 227-254).

Methods of estimating the contents of bird stomachs, W. L. McATEE (*Auk., 29 (1912), No. 4, pp. 449-464*).—This is a general discussion of methods, called forth by the decided opinions on the merits of the numerical and the percentage-by-bulk methods of estimating the contents of bird stomachs expressed in a work previously noted (*E. S. R., 27, p. 52*).

The author points out that "the principal objection to the method of reckoning the contents of bird stomachs solely by the number of individual insects or seeds, is that the method takes no account of size of the objects, and hence conveys no idea to those unacquainted with the groups concerned of the relative importance of the food elements. Size has much to do with economic status—i. e., capacity for good or harm—and it receives proper recognition only under the percentage-by-bulk system. . . ."

"Numerical notations in most cases greatly exaggerate the importance of elements of the food that have parts very resistant to digestion, a difficulty which is reduced to the minimum when proportions are estimated according to the volumes.

"Numerical systems are not sufficiently comprehensive. Finely comminuted, fleshy, or pulpy food, or food occurring in indefinite masses can not be reckoned by numbers. Under the percentage-by-bulk system, all food can be included in the computations. . . . The ideal system from the writer's point of view is one that combines the good points of both the numerical and volumetric methods—a system which, as a matter of record, counts individuals as far as possible, or at least in enough instances to assure the inclusion of typical cases, and which further estimates the proportion of all important items by bulk."

Report of the entomologist, J. B. SMITH (*New Jersey Stat. Rpt. 1910, pp. 299-373, pls. 7, fig. 1*).—During the course of nursery inspection a new tined

moth, which has since been described as *Plochoryctis tsugensis*, was found in some numbers on Japanese hemlock. A scale insect, similar in size and appearance to the San José scale, but which appears to be undescribed, was also found on Japanese hemlock. Mention is made of the possibility that the European red-tail (*Dasychira pudibunda*), a moth widely distributed in continental Europe and parts of Asia which frequently defoliates entire forest areas and is recognized as a first-class pest, ranking with the gipsy and brown-tail moths, has obtained a slight foothold in this country. This moth, which was first collected in Bergen County, N. Y., in 1908, was also taken in 1909, but was not met with during the inspections of 1910. It is a general feeder on deciduous trees of all kinds but favors the beech. Mention is also made of the collection of a European coccinellid in one nursery. Among the other insects mentioned are the shot hole borer, which was the source of considerable injury to peach trees; the grape-berry moth, which was unusually injurious; the pear psylla; and the pear midge, of which there was quite an unexpected recrudescence. A slight infestation of Lawrence pears by the pear midge resulted in their maturing in a twisted and deformed shape. In the opinion of the author the San José scale is on decline so far as its destructiveness is concerned.

The strawberry weevil was the source of considerable injury in Cumberland County and some sections of Cape May County. Observations and experiments with the peach borer and plum enicallid are reported. Among the apple insects mentioned are the apple leafhopper, codling moth, yellow-necked caterpillar, and green apple worm (*Nyctina* sp.).

Shade and forest insects, the occurrence of which is mentioned, include the elm leaf beetle; elm plant louse; white-marked tussock moth; maple false scale (*Pseudococcus accris*); cottony maple scale; tulip soft scale (*Lecanium tulipifera*); a leaf beetle (*Lina scripta*) on poplar, which was unusually destructive in nurseries and defoliated many of the smaller trees; the hickory bark beetle; bronze birch borer (*Agrilus anxius*); two-striped chestnut borer (*A. bilineatus*); giant root borer (*Prionus laticollis*); golden oak scale (*Asterolecanium quercicola*); periodical cicada; Chermes on conifers; etc.

Brief notes are also presented on the several insects injurious to field crops. Root maggot observations, by E. L. Dickerson (pp. 353-358), are incorporated in the report. Root maggots were found during the year to develop in wild radishes, thus indicating the desirability of keeping these plants in check. All the specimens reared to adults from wild radishes were *Pieris brassicae*. Indications point to the fact that while some of the flies live through the winter and oviposit in the spring, hibernation may take place in any of the larval or in the pupal stage. The Chinese mantid (*Tenodera sinensis*) was found at several points in the State where it had been introduced.

Under the heading of insecticides, analyses made of the brands of arsenate of lead offered for sale in the State are reported. A brief account is also given of tests of atomic sulphur, arsenate of iron, blackleaf 40, Nico-sul, and soluble oils, including vacuum oil, Carbolene, Scalecide, U-neek mixture, Spray-on Scale-off, and soluble paraffin.

[Sixth annual report of the department of entomology and zoology], C. J. S. BETHUNE (*Ontario Agr. Col. and Expt. Farm Rpt. 1911, pp. 25-43*).—The author mentions the occurrence in the Thunder Bay district of an army of black cutworms, which devoured vegetation of all kinds and completely destroyed the crops attacked; the serious infestation of grain bins by the saw-toothed grain beetle (*Silvanus surinamensis*); the work of the predaceous bugs *Perillus bioculatus* and *P. claudus*, which in both adult and nymph stages feed upon the eggs, larvæ, and mature forms of the Colorado potato beetle and in

some localities almost entirely destroy it; the occurrence of the cotton moth (*Alabama argillacea*); and of the subtropical moth *Erebus odora*, specimens of which were collected in Canada.

Biological observations in Europe reported by T. D. Jarvis (pp. 30-38) and a brief report of investigations by L. Cæsar (pp. 38-43) complete the report.

Third annual report of the state entomologist of Colorado for the year 1911, C. P. GILLETTE (*Ann. Rpt. Bd. Hort. Colo., 1911, pp. 99-169, pls. 5*).—This is a detailed account of the horticultural inspection work in Colorado. A report of analyses of samples of arsenate of lead and arsenite of zinc, and of state bee inspection for the year 1911 by W. Foster, are appended.

Seventh annual report of the state entomologist and plant pathologist for 1911, G. M. BENTLEY (*Ann. Rpt. State Ent. and Plant Path. Tenn., 7 (1912), pp. 60, figs. 20*).—A detailed report of the work of the year.

Amended law creating the Tennessee State Board of Entomology: Amended rules and regulations: Apiary inspection law (*Tenn. Bd. Ent. Bul. 6, 1912, pp. 63-76*).—The texts of these laws and rules and regulations are brought together.

The inspection and transportation of nursery stock in Tennessee, other States, and Canada, G. M. BENTLEY (*Tenn. Bd. Ent. Bul. 7, 1912, pp. 31, figs. 7*).—This bulletin has been prepared in response to inquiries concerning the inspection and shipment of nursery stock in the different States and Canada. It gives the names and addresses of the officials having the work in charge and contains revisions of the laws to July, 1912.

[Report of the entomologist], W. W. FROGGATT (*Rpt. Dept. Agr. N. S. Wales, 1911, pp. 52-55*).—This is a brief report of the work of the year and includes an account of the occurrence of the more important insects.

Fall manual of practice in economic zoology, II. A. GOSSARD (*Ohio Sta. Bul. 233, pp. 53-164+VII, figs. 18*).—This is the third of a series, of which the winter and spring numbers have been previously noted (*E. S. R., 20, p. 1048*). The general principles of practice are first discussed. Under the heading of farm treatment, the author considers the various enemies of field crops and remedies therefor (pp. 58-88). Enemies of orchard and small fruits and remedial treatment are discussed under the heading of orchard practice (pp. 88-151). The bulletin concludes with tabular data as to the insects of the vegetable garden.

Insect enemies of the avocado, P. CARDÍN (*Estac. Expt. Agron. Cuba Circ. 42, 1912, pp. 32-36*).—The more important insect enemies of the avocado in Cuba are the bagworm *Oiketicus poeyi*, a leaf roller, the coconut scale (*Aspidiotus destructor*) and an undetermined species of the same genus, and a leaf-cutting ant (*Atta insularis*).

Technical papers on miscellaneous forest insects.—V, A preliminary synopsis of cerambycoid larvæ, J. L. WEBB (*U. S. Dept. Agr., Bur. Ent. Bul. 20, pt. 5, tech. ser., pp. 149-155, pl. 1*).—In the preparation of the table of the superfamily Cerambycoidea, the author has studied the larvæ of 46 genera of the superfamily Cerambycoidea: 15 being in the family Lamiidæ, 18 in the family Cerambycidæ, 5 in the family Lepturidæ, 5 in the family Prionidæ, and 3 in the family Asemidæ. He proposes the raising of the primary groups Prionini, Asemini, Cerambycini, Lepturini, and Lamiini to family rank.

Relation of insects to the death of chestnut trees, A. D. HOPKINS (*Amer. Forestry, 18 (1912), No. 4, pp. 221-227, pls. 4*).—The author states that 472 insect enemies of chestnut trees have been listed, but that the so-called two-lined chestnut borer is deemed as important as all the others combined. This beetle is on the wing in May and June and deposits its eggs on the bark of

living and dying chestnut, oak, beech, and ironwood in the Southern, Middle, and Eastern States. The larvæ mine in the inner bark and outer wood in such a manner as to girdle the trees.

It is pointed out that insects are more or less responsible for primary wounds through which the spores of the chestnut blight disease find entrance to the living tissue.

**Insects bred from cow manure**, F. C. PRATT (*Canad. Ent.*, 4<sup>1</sup> (1912), No. 6, pp. 180-184).—This annotated list, which is supplementary to that published by L. O. Howard in 1901, contains 31 species of Diptera, 17 of Coleoptera, and 1 of Lepidoptera.

[Lime-sulphur wash and lead arsenates], R. HARCOURT (*Ontario Agr. Col. and Expt. Farm Rpt.* 1911, pp. 85, 86).—In continuation of investigations of the effect of adding lime to lime-sulphur, the author confirms the results previously obtained (E. S. R., 25, p. 506), finding that there is no objection whatever to the practice of adding lime to lime-sulphur spray, provided the lime is not put in until after the necessary quantity of water has been added to the concentrate to dilute it to the required strength. Analyses of 9 of the more common commercial brands of lead arsenate on the market are reported.

**The Minnesota flytrap**, F. L. WASHBURN (*Minn. State Ent. Circ.* 24, 1912, pp. 3, figs. 3).—A successful device for catching flies in enormous numbers, which has recently been constructed and put to a practical test by the Minnesota Station, is described and illustrated.

**Locusts and some of their parasites** (*Bol. Min. Agr. Indus. e Com.* [Rome], Ser. C, 11 (1912), No. 2-3, pp. 30-52, figs. 25).—This paper records observations made in 1910-11 during an invasion of the Province of Palermo, Sicily, by *Doclostaurus* (*Stauronotus*) *maroccanus*. The insect and other parasites of locusts are discussed and references given to the literature.

**The control of thrips on tomatoes**, J. R. WATSON (*Fla. Grower*, 6 (1912), No. 9, pp. 4, 5).—An outbreak of thrips (*Euthrips tritici*) over most of Florida occurred in the spring of 1912, the most serious injury being done in tomato fields and citrus groves.

"The young upon hatching at once attack the tenderest part of the blossom or bud. . . . This turns black and shrivels up. Soon afterwards the whole flower turns yellow and falls off. If this is repeated for all the blossoms on the first 3 or 4 stands (as was often the case this year) the crop is ruinously shortened."

A mixture consisting of commercial lime-sulphur 2½ qt., black-leaf 40 3½ fluid ounces, and water 50 gal., which has been used effectively against the orange thrips in California, was applied during April, 1912, and killed about 75 per cent of the thrips present.

**A new genus and three new species of North American Thysanoptera**, J. D. HOOD (*Psyche*, 19 (1912), No. 4, pp. 113-118, pls. 2).—*Heliothrips phaseoli*, one of the species here described as new, is reported as very injurious in 1908 to beans in the region of Brownsville, Texas. "Its ravages were so severe that the plants became yellowish and the crop was greatly diminished. Across the Rio Grande in Mexico, near Matamoros, it was found on a species of wild bean which grew along the river bank; and for this reason it would appear that the species is a native one which has lately turned its attention to the cultivated bean."

**Some considerations in regard to the classification of the order Thysanoptera**, R. S. BAGNALL (*Ann. and Mag. Nat. Hist.*, 8. ser., 10 (1912), No. 56, pp. 220-222).—The author erects the new suborder Polystigmata for the reception of the family Urothripidæ.

Papers on deciduous fruit insects and insecticides.—Spraying experiments against the grape leafhopper in the Lake Erie Valley in 1911, F. JOHNSON (*U. S. Dept. Agr., Bur. Ent. Bul. 116, pt. 1, pp. 13, pls. 3, figs. 3*).—This is a report of experiments conducted during 1911 in continuation of those previously noted (*E. S. R.*, 25, p. 152). Owing to the more rapid development of the immature stages of this insect in 1911 than in 1910 there was a partial second brood of considerable proportions in 1911, which greatly augmented the injury toward the ripening season.

Two forms of commercial tobacco extract were used in the experiments, the first (blackleaf extract), containing 2.7 per cent nicotine; the second (blackleaf 40), containing 40 per cent nicotine sulphate. The first, used at a dilution of 1 part of extract to 150 parts water, killed all nymphs that were thoroughly wet with the spray, especially the smaller nymphs, between the first and fourth molts. The second was effective at a dilution of 1 part extract to 1,500 parts water.

"The field experiments made during the season . . . show that a single application of the tobacco extracts applied against this insect in the nymphal stage as a contact spray will reduce its numbers to such an extent that the infested vines will remain in good foliage throughout the season and mature a crop of high-quality fruit.

"As indicated by the variation in the time and rapidity in development of the nymphs in 1910 and 1911, it is evident that no definite date for making the spray application can be given. Where the winged adults are at all numerous in the early part of the season the vineyardist is urged to examine the underside of the grape leaves toward the middle and the end of June and to observe the number and size of the nymphs. The spray application to be most effective should be made at about the time the first nymphs to hatch are near the last molt. This is indicated by the length of the wing pads. At this time the underside of badly infested leaves will be covered by the nymphs in all stages of development. Generally speaking, this condition is likely to occur in the Lake Erie Valley from July 1 to 15. All of the field experiments conducted in 1910 and 1911 were made between these dates and in every instance very satisfactory results were secured."

The aphids attacking *Ribes*, with descriptions of two new species, F. V. THEOBALD (*Jour. Econ. Biol.*, 7 (1912), No. 3, pp. 94-116, pls. 2, figs. 14).—Seven species which attack cultivated and wild currants and gooseberries are dealt with, namely, *Aphis grossularia*, *Macrosiphum lactuce*, *Rhopalosiphum lactuce*, *R. brittanii* n. sp., *Myzus ribis*, *M. whitei* n. sp., and *Schizoneura ulmi*.

Recent results of spraying experiments for the control of the white fly on citrus, W. W. YOTHERS (*Proc. Fla. State Hort. Soc.*, 24 (1911), pp. 53-64).—This paper gives further information as to the value of the formulas previously recommended (*E. S. R.*, 25, p. 153) when used in combating the white fly.

The biology and the treatment of the eudemis and cochyliis moths in 1911, J. CAPUS (*Rev. Vit.*, 37 (1912), Nos. 959, pp. 593-600; 960, pp. 633-638; 961, pp. 681-686; 962, pp. 707-712; 964, pp. 773-778; 965, pp. 818-821; 966, pp. 846-851).—This article reports investigations of the biology of and remedial measures for the cochyliis and eudemis moths.

A fungus disease of bagworms (*Isaria psychidæ*), I. B. P. EVANS (*Agr. Jour. Union So. Africa*, 4 (1912), No. 1, pp. 63-67, fig. 1).—The author's studies show that the fungus *I. psychidæ* caused a disease among the bagworms from which, when once infected, there was no chance of recovery. Experiments conducted in the laboratory showed that if healthy bagworms were fed on wattle leaves contaminated with the spores or germs of the fungus, the insects contracted the disease in from 4 to 5 days' time and were dead at the end of 7 to

10 days; in less than a month's time the characteristic white fungus cushions had appeared and pushed their way through the bags to the exterior. The results thus far obtained indicate that the pest may be greatly diminished by the use of this fungus.

**On the history of the nonne disease, C. VON TUBEUF** (*Naturw. Ztschr. Forst- u. Landw.*, 9 (1911), No. 8, pp. 357-377).—This is a review of investigations made of the wilt disease of the nun moth.

**Report on the mosquito work for 1910, J. B. SMITH** (*New Jersey Stas. Rpt. 1910*, pp. 377-424, pls. 3, fig. 1).—This is a somewhat detailed report of the work of the year, and includes reports on local conditions and on *Azolla* investigations previously noted (*E. S. R.*, 24, p. 562). Brief notes on the habits of certain mosquitoes are appended.

**Fruit fly campaign, W. M. GIFFARD** (*Hawaii, Forester and Agr.*, 9 (1912), No. 8, pp. 236-239).—A peculiar condition affecting a large percentage of mango fruits during the present season, at first supposed to have been due to the attack of the Mediterranean fruit fly, has been found to be caused by the mango weevil. The attack of this weevil, which has been exceedingly prevalent throughout Honolulu, is said to bring about fermentation and subsequent rotting of the fruit.

**Fannia (Homalomyia) canicularis and F. scalaris, C. G. HEWITT** (*Parasitology*, 5 (1912), No. 3, pp. 161-174, pl. 1, figs. 7).—This is an account of the bionomics and of the larvæ of these flies and their relation to myiasis of the intestinal and urinary tracts.

**Life history and habits of the "Cayor worm," the larva of Cordylobia anthropophaga, an African muscid, E. ROUBAUD** (*Compt. Rend. Acad. Sci. [Paris]*, 153 (1911), No. 17, pp. 780-782; *abs. in Science*, n. ser., 35 (1912), No. 904, pp. 662, 663).—A report of biological studies of a dipteran the larva of which is a cutaneous parasite.

**A catalogue of the Coleoptera (Coleopterorum Catalogus. Berlin, 1911, pts. 37, pp. 587-742; 38, pp. 100; 1912, pt. 39, pp. 574).**—In continuation of this work (*E. S. R.*, 26, p. 560), part 37, by H. Gebien, completes and indexes the subfamilies, genera, and subgenera of Tenebrionidæ, and also catalogues the Tricetonotomidæ; part 38, by J. J. E. Gillet, catalogues the scarabæid subfamily Coprinae, I; and part 39, by C. Aurivillius, the subfamily Cerambycinae.

**Annual report of the Bee-Keepers' Association of the Province of Ontario, 1911 (Ann. Rpt. Bee Keepers' Assoc. Ontario, 1911, pp. 103).**—This report consists of the proceedings of the association.

**The lore of the honeybee, T. EDWARDES** (*New York, 1911, pp. XIX+196*).—A popular work.

**The life history of Nosema apis, and the significance of the various stages of the parasite in the disease, H. B. FANTHAM and ANNIE PORTER** (*Jour. Bd. Agr. [London]*, 19 (1912), No. 2, Sup., 8, pp. 57-78, pls. 3).—The life cycle of *N. apis* in the adult bee is summarized by the authors as follows:

"When the spore is taken up mixed with food, it generally passes forwards into the chyle stomach of the bee before much change occurs in it. Within the chyle stomach the spore wall is softened by the action of the digestive juice of the bee, which penetrates to the spore contents. Stimulated by the juice, the sporoplasm apparently presses the vacuole, with the result that the polar filament is forcibly ejected. It serves for a short time as an organ of attachment, fixing the spore to the gut wall. The sporoplasm concentrates and moves forwards, whereby the polar filament is forced still farther outwards, and becomes disconnected from the spore. The sporoplasm, retaining 2 of the nuclei, creeps out from the sporocyst, leaving the 2 sporocyst nuclei behind. The free sporoplasm becomes amoeboid. The binucleate amoebula creeps about over the in-

testinal surface. The nuclei may fuse, or more often, the amœbula proceeds to form daughter amœbulae. The final active amœbulae are small, roundish organisms, each with a single nucleus containing a karyosome. Each amœbula is capable of amœboid movement. It penetrates the cells of the gut, or else between them, and finally either enters one of the cells or goes beyond and floats in the hæmocœlic fluid.

"Assuming that it enters an epithelial cell of the gut, it becomes rounded and passive therein, and after a period of growth, during which time it is known as a trophozoite, commences to multiply by several methods. There results usually a collection of separate daughter individuals or meronts, or chains of meronts. The chain condition is somewhat less common than the separate forms in our experience so far. Each meront is uninucleate. Alternatively, a meront may form a large, multinucleate body, in which cleavage into daughter meronts does not occur. Such bodies may be intercellular or intracellular.

"After a period of active growth and division producing uninucleate meronts, spore formation begins. The organism is now called a pansporoblast. Active amitotic nuclear division occurs, resulting in the production of 5 nuclei. Two vacuoles also form in the developing spore, a large one at one end called the posterior vacuole, and a small one at the opposite end, forming the polar capsule. The living body substance or sporoplasm then forms a somewhat ring-shaped mass between the 2 vacuoles, and in it are lodged the 5 nuclei arising by division from the meront nucleus. Two migrate to the sides. These become elongated, and may be termed the sporocyst nuclei. Of the other 3 nuclei, 1 controls for a time the polar capsule, and the other 2 the sporoplasm. The polar capsule gradually forms the spiral polar filament, which extends down into the posterior vacuole. While these nuclear changes are taking place in the sporoblast or young spore, the latter is forming a coat around itself. This spore coat or sporocyst gradually thickens and obscures the nuclei beneath, and the final result is that from one pansporoblast a single spore, resembling a rice grain in shape, with a shining refractile sporocyst is produced. In this condition the spore passes into the lumen of the gut, is voided with the feces, and remains a source of infection for some time.

"It will thus be realized that there are 2 distinct phases in the life cycle of *N. apis* within the bee. This feature *Nosema* holds in common with other protozoal parasites, such as the coccidium fatal to game birds and poultry. The first part of the life of *Nosema* is occupied in growth and active division, so that the number of parasites within the host is enormously increased. This multiplicative stage, known as merogony, is the one that is most dangerous to the host. The young stages of the parasite alone are sufficient to kill the bee in many cases, and the parasite as a result may never reach the final or spore stage of its development. Young grouse similarly are killed by the multiplicative stages (merozoites) of *Eimeria* (*Coccidium*) *arivum*.

"When the power of the parasite to multiply more in the one host is exhausted or when the bee can no longer supply it with sufficient food, it becomes necessary for the *Nosema* to leave its host and to renew its development in a new one. Consequently, the parasite must protect itself in order to survive the period between leaving one host and entering the next. As a result of this need the parasite forms a hard outer covering or spore coat, and becomes a spore. The spores are highly resistant to outside conditions, can live for some time without losing their infective power, and so can become new sources of infection for other bees. In other words, merogony of *N. apis* serves for the infection of, and has fatal effects on, a single host; sporogony is a means for the spread of the disease to new hosts."

The authors consider it probable that the cycle in the larvæ follows on exactly the same lines as in the adult.

The morphology and life history of *Nosema apis* and the significance of its various stages in the so-called Isle of Wight disease in bees (Microsporidiosis), H. B. FANTHAM and ANNIE PORTER (*Ann. Trop. Med. and Par.*, 6 (1912), No. 2, pp. 163-195, pls. 3, fig. 1).—The information here presented is included in the article above noted.

The ways in which the disease [*Nosema apis*] may be spread, G. S. GRAHAM-SMITH and G. W. BULLAMORE (*Jour. Bd. Agr. [London]*, 19 (1912), No. 2, Sup. 8, pp. 95-118, fig. 1).—"We have shown that the infection may be transmitted through the agency of infected foods or of living infected bees. Infected water, especially rain water grossly contaminated with excrement in the vicinity of hives, and honey, present in hives in which bees have died, seem to be the most important infected foods. Foraging bees infected by ingesting these foods, and 'parasite carriers,' whether queens, drones, or workers, are the most important agents of infection. The latter may be present in stocks which have never suffered from the disease, or in dwindling stocks showing few symptoms, or in stocks which have suffered from the disease and apparently recovered."

The dissemination of *Nosema apis*, H. B. FANTHAM and ANNIE PORTER (*Ann. Trop. Med. and Par.*, 6 (1912), No. 2, pp. 197-211, figs. 2).—This article is based upon the paper noted above.

The relation of *Nosema apis* to the Isle of Wight disease, G. S. GRAHAM-SMITH, H. B. FANTHAM, and ANNIE PORTER (*Jour. Bd. Agr. [London]*, 19 (1912), No. 2, Sup. 8, pp. 39-56, pl. 1).—"Taking into consideration the following facts, namely, that *N. apis* is met with in 84 per cent of stocks reputed to be suffering from the disease, that infection experiments have proved that the parasite produces a fatal disease in bees, that very marked destruction of the tissues of the alimentary tract is found in severely infected specimens, whether the condition has been produced experimentally or naturally, and that in less marked infections a high proportion of the cells lining the alimentary tract are invaded by the parasites and injured, the writers consider themselves justified in taking the view that *N. apis* is the causative agent in most outbreaks of disease in which the Isle of Wight symptoms are present. . . .

"Experiments have conclusively proved that the spores are capable of producing a fatal disease in healthy bees, but no such experiments have been undertaken with young stages of the parasite only, and up to the present we have no evidence that the young stages are capable of causing infection when fed to healthy bees, although bees in which the young stages only are found die in large numbers. . . . It seems to the writers extremely probable that many of the stocks which recover become partially immune, at any rate for a time, to the effects of the parasite, but still continue to harbor it, and are consequently a source of danger to the noninfected stocks in the neighborhood."

Microsporidiosis in other Hymenoptera.—Infection experiments and observations, G. S. GRAHAM-SMITH (*Jour. Bd. Agr. [London]*, 19 (1912), No. 2, Sup. 8, pp. 131, 132, pl. 1).—It is pointed out that while the experiments here reported indicate that wild bees and wasps may act as parasite carriers, it has not yet been shown that the *Nosema* found in naturally infected humblebees is *N. apis*.

Microsporidiosis, a protozoal disease of bees due to *Nosema apis*, and popularly known as Isle of Wight disease, H. B. FANTHAM and ANNIE PORTER (*Ann. Trop. Med. and Par.*, 6 (1912), No. 2, pp. 145-160, fig. 1).—This paper relates to the investigations above noted.

**A contribution to the knowledge of *Nosema bombycis*, J. OHMORI (Arb. K. Gsndhtsamt., 40 (1912), No. 1, pp. 108-122, pls. 2).**—This is a report of studies of the structure and development of *N. bombycis*, the cause of pebrine in the silkworm, conducted in 1910-11 at the Protozoan Research Laboratory of the Royal Health Department in Berlin.

**The poultry tick, D. F. LAURIE (Jour. Dept. Agr. So. Aust., 15 (1912), No. 12, pp. 1251-1258; 16 (1912), Nos. 1, pp. 10-19, figs. 14; 2, pp. 111-120, figs. 17).**—An account of the life history and bionomics and of preventive and remedial measures for *Argas miniatus*. In tests made to determine the efficacy of certain preparations in destroying the fowl tick, which are here reported in tabular form, kerosene oil appeared to be the most effective and cheapest.

### FOODS—HUMAN NUTRITION.

**The floating of oysters, J. NELSON (New Jersey Stas. Rpt. 1910, pp. 209-217).**—The results reported seem in the author's opinion to favor the practice of "floating" oysters, which is widely prevalent in the North. Oysters are kept on submerged floats in water less salt than that of the beds during from 2 to 4 changes of tide, during which time they draw in water as when on the original beds. This process is called "floating," "giving the oysters a drink," "freshening," and "fattening." The resulting advantages are said to be removal of the mud, increased volume of the flesh of the oyster, improvement in color and texture, decrease in amount and rapidity of shrinkage, and better retention of water content in transport and storage.

In the experiments here reported, half of the sample from each bed was floated, then compared with the half not so treated. The results of 25 selected experiments are presented. Except in the case of certain ones injured in handling, oysters were found to regulate the amount and quality of the water they "breathe," opening only when the incoming tide brings water containing a certain proportion of salt, and refusing to open in fresh water. The process of floating enabled the oysters to rid themselves of the dirt brought from the beds, hence the floated product appeared cleaner. An improvement in color was also noted.

"When unfloatoed oysters were shucked in comparison with floated ones, and the 2 lots were left a few hours in their natural liquor, the former secreted liquor the more rapidly, and also considerable slime, in which the coarser part of the dirt became entangled. This slime became stringy, and the liquor turbid and repulsive, due to the dirt that was mixed with it.

"In strong contrast, was the clean and appetizing appearance of the floated lot; here, at first, the liquor was rather small in amount, but as much as in the former case was finally pressed out, through contraction of the tissues. It seemed that the total slime in the two cases was finally approximately equal, though at the start, the floated lot seemed to be the more slimy."

It is claimed that no deception is involved in the process, since it seems to be impossible to improve the appearance of a poor oyster by it. Water entering the tissues, as it does in the process of floating, is more firmly retained than that held by capillary attraction in the channels of the body, and much more firmly than that between the oyster and the shell. This retained water, the author believes, improves the keeping and cooking qualities. No significance is attached to the loss of flavor, as this is said to be due merely to loss of salt which can easily be replaced before serving. It appears to be impossible to have the floats near the beds, or at least it is much more convenient to have them near the store-houses. The author concludes that the practice of float-

ing is not injurious if the water in which the oysters are floated is pure, and that the practice is desirable on account of the improvement in the oyster. It is suggested that both floated and unfloated oysters be admitted to the market, since a demand for both kinds exists, and in time the demand for the floated product will be so great as to give it the greater value.

The author notes that the experiments are rather limited and that a more prolonged study of the question may be desirable.

**Decay and preservation of eggs,** A. KOSSOWICZ (*Monatsh. Landw.*, 5 (1912), No. 2, pp. 43-49; *abs. in Schweiz. Wchnschr. Chem. u. Pharm.*, 50 (1912), No. 28, p. 420).—Contamination of the egg by micro-organisms may occur while in the ovarian duct, but not after it is laid until age causes loss of resistance.

No organisms had entered eggs 4 weeks old; only *Cladosporium herbarum* had entered after 8 weeks, *Phytophthora infestans* after 12 weeks, and *Rhizopus nigricans* after 5 months. The germicidal power of the albumin decreases rapidly with age. In addition to his own work the author summarizes data from a large number of experiments by others.

**Curing of Italian hams,** J. A. SMITH ET AL. (*Daily Cons. and Trade Rpts. [U. S.], 15 (1912), No. 249, pp. 385-388*).—Methods of curing hams in different parts of Italy are given in detail.

**Mince-meat and mock mince-meat** (*Pure Products*, 8 (1912), No. 10, pp. 555-557).—The results of the examination of about 500 recipes for mince-meat are given and suggestions for another standard are made.

**The manufacture of gelatin,** L. A. TITTELE (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 6, pp. 446-451, figs. 4, *diagms.* 3).—This description of the manufacture of gelatin treats of cleaning the raw material, dissolving the gelatin, concentrating the solution, chilling and spreading, drying, and finishing (grinding and packing). Curves show the imports of gelatin and price fluctuations during the past 8 years.

**High fat standard for ice cream,** M. MORTENSEN (*N. Y. Produce Rev. and Amer. Cream.*, 34 (1912), No. 17, p. 754).—Standards and definitions are suggested favoring a high fat content (at least 12 per cent) of butter fat in ice cream.

**Wheat and flour,** R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm.*, 37 (1911), pp. 73-84).—In continuation of earlier work (E. S. R., 25, p. 564), experiments with wheat and flour were carried on. A comparison of commercial flours (patent and bakers' grades), freshly ground from the crop of 1911 wheat, showed that such flour was only slightly lower in gluten and in water absorption, and in yield of bread and size of loaf was fully equal to the 1910 crop, while some superiority in the texture of the crumb was noted.

Baking tests with winter wheats grown on experimental plats and ground in a small mill showed superiority in the 1911 crop over that of 1910. "With 2 or 3 exceptions the loaf was larger and the crumb of the bread was better, both in color and in texture." The apparently better results obtained from the 1909 crop, as compared with those of 1910 and 1911, was partly due, in the author's opinion, to longer aging.

Baking tests with Ontario spring wheats grown on experimental plats showed that, in the majority of cases, the 1910 crop contained less gluten than that of 1909, while the reverse was the case with regard to absorption. "The yield of bread, consequently, is higher, but the volume of the loaf is less. Generally speaking, the quality of the bread from the 1910 crop is inferior to that of the 1909."

As regards varieties, the old Red and White Fife wheats still hold a good place, while Preston Spring, Gatineau, and Hungarian gave a rather larger volume of loaf of about equal quality.

Baking tests reported with sprouted wheat represent work by A. J. Galbraith and submitted in a thesis. Ontario soft winter wheat and Manitoba spring wheat of medium grade were selected. Samples, allowed to germinate until the sprouts were equal to the length of the kernel, to about twice the length of the kernel, and to about  $1\frac{1}{2}$  inches long, were compared with ungerminated wheats. As was expected, the flours from these wheats "showed considerable difference in appearance. That from the least sprouted wheat had the best color, while that from the more extended germination was very dark. On washing out the gluten it was found that the flour from the wheat with the shortest sprouts handled quite normally. The gluten from the second sample was rather soft and runny, and the third was so poor that it was impossible to make a satisfactory determination of the amount of it present."

The bread-making tests showed that the flour from wheat which was least germinated yielded bread superior in color, texture, and general appearance of the loaf to that obtained from the normal unsprouted wheat. The more extended germination allowed in the other wheats injured the quality of the gluten and apparently more in the case of the winter than of the spring wheat.

A study of the nitrogen of the sprouted and unsprouted wheats showed that "the quantity of alcohol-soluble nitrogen is apparently not influenced by the germination, but the salt-soluble compounds are slightly, and the amids very materially affected." While it was not possible to study definitely the effects of the nitrogen compounds on the bread-making quality of the flour, "the results do show that while the alcohol-soluble and gliadin nitrogen remains unchanged, the amount of glutenin nitrogen decreases and the amid nitrogen increases. Apparently the destruction of the gluten is accompanied by these changes."

A study of the carbohydrates showed that, as might be expected, "the percentage of starch present in the grain decreases and the soluble carbohydrates increase. These soluble carbohydrates and the soluble protein are essential food constituents of the yeast, and possibly the better quality of bread obtained from the slightly sprouted wheat was due to the extra food materials present. On the other hand, too large an amount of the soluble carbohydrates in the flour or dough is always associated with a poor color and texture of bread, and even if the gluten was not destroyed by the longer germination, it is probable that the bread made from these samples would not have been so good as that obtained from the normal wheat. Apparently the bread-making value of the wheat is improved by germination provided this is not continued too far. When this has taken place, the dough 'works' very fast, doubtless due to the large amount of available food present, but the dough will not 'rise' properly because the gluten, or, at least, the tenacious nature of the gluten, has been destroyed."

**How bread becomes stale**, J. R. KATZ (*Pharm. Weekbl.*, 49 (1912), No. 27 pp. 618-631).—From various experiments it appears that bread in becoming stale loses but little water, the crumb losing from 1 to 2 per cent but the crust gaining from 8 to 9 per cent. There is a decrease in the amount of water-soluble dextrins in the crumb, the crust remaining almost unchanged.

Reheating appears to restore to stale bread many of the properties of fresh bread. Apparently the degree of staleness is determined by the presence of some compound which is unstable at high temperatures.

**The bacterial contamination of bread**, KATHARINE HOWELL (*Amer. Jour. Pub. Health*, 2 (1912), No. 5, pp. 321-324; *abs. in Med. Rev. of Reviews*, 18 (1912), No. 9, pp. 589, 590).—One hundred loaves of bread, wrapped and unwrapped, were collected from shops in Chicago. Dirty loaves gave an average bacterial count of 64,970 per loaf, loaves from fairly clean shops 3,117,

and from thoroughly clean shops 835. None of the dirty shops kept wrapped bread. Wrapped bread from fairly clean shops showed a count of 848, and from the best shops 371.

**Yoghourt bread** (*Pure Products*, 8 (1912), No. 10, p. 560).—The substitution of milk containing the *Bacillus bulgaricus* for part of the water used in bread making is said to give a pleasant and characteristic flavor, especially in the case of rye bread.

**Natural pure culture and yoghurt making**, W. HENNEBERG (*Ztschr. Spiritusindus.*, 35 (1912), Nos. 30, pp. 405, 411; 31, pp. 415, 416; 32, pp. 427, 428; 34, p. 454).—Experiments are reported which have to do with the cultivation of the yoghurt bacillus by dry and wet methods.

**On a new glucolytic ferment of yeast**, V. BIRCKNER (*Jour. Amer. Chem. Soc.*, 34 (1912), No. 9, pp. 1213-1229).—The ferment which occurs in California "steam beer" yeast accelerates the decomposition of glucose at high temperatures; is active at 70° F.; is not zymase; causes no gas formation; yields no alcohol; rapidly darkens glucose at 70°, giving a strongly acid reaction with gradual formation of a caramel-like deposit; is stable at room temperature in aqueous solution; is not destroyed by boiling; is active in neutral or acid solution against glucose, polyphenols, and lactates; contains no tyrosinase; does not act as a peroxidase against glucose; gives a strong pyrrol reaction; and appears to belong to the zymases although having some characteristic of the oxidases. The cleavage products are mostly acid and contain pentose and formaldehyde.

**[Macaroni]**, L. LODIAN (*Amer. Miller*, 40 (1912), No. 10, pp. 786, 787).—This is a description of macaronis made from beans, buckwheat, whole wheat, rice, wheat and rice, milk (casein), chestnuts, tree pith, and seaweed.

**On the starch of glutinous rice and its hydrolysis by diastase**, Y. TANAKA (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 8, pp. 578-581).—Instead of a blue coloration, the starch of glutinous rice gives a red coloration with iodine, due to the characteristic nature of the starch itself, and not to the presence of dextrans or albuminoids.

The glutinous rice starch contains none of the common starch which gives a blue coloration with iodine. The glutinous rice starch is rapidly hydrolyzed by diastase to dextrin with less production of maltose than given by potato or common rice starch. The author believes that the glutinous rice starch contains amylopectin or other analogous constituent which produces a dextrin less rapidly hydrolyzed than ordinary starch by diastase. Several other cereals were found to contain a similar starch.

**Nutritive value and use of soy beans as food**, H. NEUMANN (*Berlin. Klin. Wchnschr.*, 49 (1912), No. 36, pp. 1710-1714).—Conclusions favorable to the use of soy beans are drawn from the author's tests and a summary of the work of others.

The author notes that he found soy beans to increase the milk of nursing women.

**Concerning the sugar content of watermelons**, C. P. SHERWIN and C. E. MAY (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 8, pp. 585-588).—Analyses were made of unusually sweet watermelons with thin rinds.

They had 43 per cent juice, 47 per cent rind, and 10 per cent pulp; the ash content was about 0.25 per cent of the juice,  $\frac{1}{3}$  of the ash being insoluble. Fermentation of the sugar produced a 2.5 per cent alcohol solution by weight, and from the fermented juice a 1.75 per cent acetic acid solution. The Fehling titration method showed 5.5 per cent of reducing sugar in the juice, and the polariscope a smaller quantity. About 1 per cent of the juice was sucrose.

The palm cabbages of Madagascar, H. JUMELLE and H. P. DE LA BATHIE (*Compt. Rend. Acad. Sci. [Paris]. 155 (1912). No. 13, pp. 587-589*).—A brief description of several Madagascan varieties of palm having edible heads is given.

Cholera and tomatoes, R. RICCIARDELLI (*Bol. Chim. Farm., 50 (1911), pp. 573-575; abs in Ztschr. Untersuch. Nahr. u. Genussmtl., 24 (1912), No. 3, p. 250*).—According to the author, the acid content of tomatoes (0.81 per cent citric acid, with traces of tartaric, malic, and oxalic acids) acts as an intestinal disinfectant.

Vegetables and typhoid fever (*Brit. Food Jour., 14 (1912), No. 161, p. 83*).—Quoting from the *Medical Press*, experiments are reported in which typhoid bacilli were found on lettuce grown in soil inoculated with the culture 31 days before gathering the plants.

Three consecutive washings in distilled water failed to remove the bacilli entirely. The dangers of using uncooked vegetables and of using human excreta as a fertilizer are emphasized.

The relatively high dextrose content in certain preserved fruits, FAVREL and GARNIER (*Jour. Pharm. et Chim., 7. ser., 4 (1911), No. 6, pp. 253-255; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 24 (1912), No. 7, p. 473*).—Determinations of the different sugars in dried apricots and mirabelle plum juice are reported and the results discussed with reference to the preserved fruits.

Commercial table sirups and molasses, W. FREAR (*Penn. Dept. Agr. Bul. 224, 1912, pp. 97*).—From an extended study, including the examination of a large number of samples of table sirups and molasses on sale in Pennsylvania, a number of general conclusions were drawn, from which the following are quoted:

"The goods sold as 'maple sirup' are, with few exceptions, true to name. . . . The sirups labeled 'maple and cane' or 'cane and maple', usually contain only small proportions of the maple product. There is little sugar cane sirup on the market.

"The molasses on sale is practically confined to the products of the modern sugar-house. The 'New Orleans molasses' of to-day differs materially in flavor, sugar richness, and probably also in acidity from the older 'open kettle' product formerly sold under that name. The ash limits for table molasses are exceeded in but few cases, but the organic solids not sugar are, in some cases, so high as to suggest that the molasses in these cases is of very inferior grade. The quantities of sulphur dioxid are usually not high. The presence of tin and zinc in small quantities is common, and, in the latter case, suggests the need for greater care in cleansing before filling the tins in which these goods are usually retailed.

"The samples of refined molasses submitted were too few to permit any judgment of their average quality as compared with that of the ordinary molasses.

"The 'corn sirup with cane flavor' and 'compound molasses' formed a large fraction of the 'table sirups' on sale. The goods of the former class frequently lack cane flavor, in the literal sense of the term. The proportions of glucose claimed on the labels are rarely exceeded in the goods. As a class, these goods contain more water than should be introduced in the ingredients named. The proportions of sulphur dioxid present are, as a rule, very low, indicating that the glucose now used for these mixtures is practically free from this constituent, which was formerly found in larger amounts.

"Sulphur dioxid appeared, in a few cases, in classes of sirups not covered by the proviso of the food law that tolerates it, within certain limits and under certain conditions, in molasses.

"In no case was saccharin, benzoic acid, or salicylic acid found present.

"The labeling of many of . . . [the] samples [examined] was open to objection."

The rôle of caffeine in the cardiac action of coffee, H. BUSQUET and M. TIFFENEAU (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 5, pp. 362-365).—From experiments with isolated rabbit heart and with a dog the authors conclude that caffeine is apparently the principal agent in the cardiac action of coffee.

Coffee substitute, L. FARCY (*Ann. Falsif.*, 5 (1912), No. 45, pp. 361, 362, figs. 4).—A Swiss coffee substitute was found by chemical and microscopical examination to contain about 50 per cent of caramel, 25 per cent of chicory, from 10 to 12 per cent of parched barley, and about the same amount of coffee.

"Ochsena", a so-called vegetable meat extract, C. REESE and J. DROST (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 24 (1912), No. 3, pp. 240-244).—Analytical data are reported and discussed.

Regulation regarding tinning of culinary utensils, A. GAUTIER (*2. Cong. Internat. Hyg. Aliment. Bruxelles [Proc.]*, 1 (1910), Sect. 3, pp. 57-62; *Bul. Soc. Sci. Hyg. Aliment.*, 1 (1911), No. 1-2, pp. 189-193).—Laws prescribing the permissible proportion of lead in tin plate of culinary utensils in France, Germany, Belgium, and other countries are cited. England has no such laws.

The permissible amount is deemed from  $\frac{1}{2}$  to 1 per cent of lead. Five per cent has been found to be injurious, and in tinning of soldered utensils the tinning bath may gradually acquire as much as this from the solder. The author believes that the French regulation, permitting the use of tinning baths containing  $\frac{1}{2}$  per cent of lead, is reasonable.

Rules and regulations for carrying out the provisions of the food and drug law of Connecticut—revision of January 1, 1912 (*Hartford, 1911*, pp. 36).—Detailed instructions for carrying out each of the regulations are given.

Laws of Wyoming providing for pure food, drugs, drink, and illuminating oils (*Chycenc. Wyo.*, 1911, pp. 16).—The laws of Wyoming relating to the manufacture and sale of foods, drugs, beverages, and illuminating oils are given.

Eighteenth annual report of the dairy and food commissioner of the State of Michigan for the year ending June 30, 1911, G. M. DAME (*Ann. Rpt. Dairy and Food Comr. Mich.*, 18 (1911), pp. 192).—This volume contains new legislation relating to the sale of adulterated candies, advice on the care of milk in hot weather, reports of food, dairy, drug, and apiary inspections, the state analyst's report of analyses of miscellaneous foodstuffs and feeds, and other similar data.

Preliminary report of the dairy and food commissioner for the year 1911, J. FOUST (*Penn. Dept. Agr. Bul.* 221, 1912, pp. 45).—This report contains expositions of the State pure food laws passed in 1911, relating to sausage, milk, and cream. Brief summaries of inspections of various foodstuffs are also given.

Feeding children for efficiency, W. S. CORNELL (*Forecast*, 4 (1912), No. 4, pp. 125-128, figs. 2).—Arguments for the school lunch are presented, with sample menus of meals that can be served for 3 cts.

Tests with 362 children are referred to which indicate that those who received school lunches gained considerably more in physical measurements (weight, height, hand strength, and lung capacity) during 6 months, than those who did not receive the lunches. Tests with 40 other children for 3 months showed that the fed children gained slightly more than the unfed in lesson and conduct averages.

Some fundamental principles in studying infant metabolism, F. G. BENEDICT and F. B. TALBOT (*Amer. Jour. Diseases Children*, 4 (1912), No. 3, pp. 129-

136, figs. 4).—Work of previous experimenters is criticized on the ground that sufficient account has not been taken of muscular activity.

In the experiments here described graphic records of muscular activity were made. The periods of observation were short and as far as possible while the infants were asleep. The energy measurements were made indirectly by measuring the gaseous exchange.

A close relation was found between carbon dioxide production, pulse rate, and muscular movements. The pulse rate in the younger infants was much less stable than in the older infants, the slightest motion causing marked increase of the rate. A description and a diagram of the apparatus used are given.

A consideration of some chemical transformations of proteins and their possible bearing on problems in pathology, F. P. UNDERHILL (*Arch. Int. Med.*, 8 (1911), No. 3, pp. 356-381).—Chemical changes in proteins during the process of digestion are considered, together with their possible relation to pathological conditions.

The sparing value of fats, A. BARTMANN (*Ztschr. Biol.*, 58 (1912), No. 8-11, pp. 375-419, *dgms.* 5).—Experiments in which dogs were fed lard and later raw fat pork showed that the sparing value of fat was constant, being about 7 per cent.

An efficiency curve of the fat was obtained by plating the sparing value against the amount fed. This curve reaches its maximum at about 150 per cent of the necessary energy supply. Feeding large amounts of fat caused increased elimination of nitrogen through the alimentary tract.

Water balance in rest and in mountain climbing, G. GALEOTTI and E. SIGNORELLI (*Biochem. Ztschr.*, 41 (1912), No. 3-4, pp. 268-286).—Water excretion through the kidneys, lungs, and skin was not affected by altitude alone, but in mountain climbing as much as 4.2 liters passed through the skin in a day. The weight so lost was quickly regained.

The physiological significance of the segmented structure of the striated muscle fiber, R. L. LILLIE (*Science, n. ser.*, 36 (1912), No. 921, pp. 247-255).—In this paper two views of the cause of muscular contraction are contrasted, namely, that the process is analogous to the absorption of water by a sheet of acidulated gelatin, and that the process results from transformation of surface energy of the ultimate structural elements or colloidal particles (submicrons) composing the fibrils.

A comparative study of temperature fluctuations in different parts of the human body, F. G. BENEDICT and E. P. SLACK (*Carnegie Inst. Washington Pub.* 155, 1911, pp. 73, figs. 38).—The purpose of these investigations was to determine the best place for accurate and constant measurement of body temperature, the temperature gradient of the body, and whether or not the temperature fluctuations are uniform in different parts of the body. The thermal junction apparatus used is described in detail.

The conclusion is reached that, aside from the skin temperature, the temperature of the rectum or of the vagina is the best index of body temperature.

A bicycle ergometer with an electric brake, F. G. BENEDICT and W. G. CADY (*Carnegie Inst. Washington Pub.* 167, 1912, pp. 44, figs. 16).—An apparatus designed to measure the amount of mechanical work done by a man, and essentially the same as that in use at this Department (E. S. R., 21, p. 68), is described. It consists of a bicycle the rear wheel of which is a copper disc, rotating between the poles of an electro-magnet. The calibration of the instrument is described and a study reported of the magnetic reactions in the disc.

## ANIMAL PRODUCTION.

The principles of Mendelian inheritance and their cytological foundation, F. PÉCHOUTRE (*Rev. Gén. Sci.*, 23 (1912), No. 16, pp. 613-623, figs. 3).—This is a review and critical discussion of Mendelism, with special reference to the function of the chromosomes.

Gametic coupling as a cause of correlations, G. N. COLLINS (*Amer. Nat.*, 46 (1912), No. 550, pp. 569-590).—It is pointed out that the theory that the various degrees of association in gametic coupling fall into a regular series, represented by powers of two, has been accepted without adequate analysis of data. To overcome the lack of a standard for making comparisons the author advocates the use of Yule's coefficient of association.<sup>a</sup>

From studies of maize and other hybrids the author finds that in several cases correlations are reversible, depending on the way the characters were combined in the parents. This fact makes it necessary to assume that characters which at one time attract each other, at other times exhibit repulsion.

The general conclusion reached is that associations between characters, like the appearance of single characters, may arise at different stages in the ontogeny of the individual.

Another view of sex-limited inheritance, R. M. STRONG (*Science, n. ser.*, 36 (1912), No. 927, pp. 443-445).—In the first generation of crosses with white ring doves (*Turtur alba*) and blond ring doves (*T. risorius*) the hybrids resembled one parent or the other in equal numbers. The blond hybrids were mostly males and the white hybrids were all females. When these latter were crossed back on white males only white offspring were obtained, and are therefore so-called extracted recessives. An explanation is given to account for these results without assuming that the male is homozygous for sex and the female heterozygous, or that a spurious allomorphy may exist with the consequence that certain sex and somatic factors may not be present in the same gamete.

Another sex-limited character, E. N. WENTWORTH (*Science, n. ser.*, 35 (1912), No. 913, p. 986).—The rudimentary mammae located on the scrotum of the male and on the inside of the thigh of the female swine appear to be a case of sex-limited inheritance in a manner similar to the inheritance of the horns in Wood's crosses in sheep (*E. S. R.*, 22, p. 378).

The genetic factors in the development of the house mouse which influence the coat color, A. L. HAGEDOORN (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 6 (1912), No. 3, pp. 97-136, pl. 1).—A detailed study of the inheritance of coat color in over 6,000 animals.

The sex ratio in hybrid rats, HELEN D. KING (*Biol. Bul. Mar. Biol. Lab. Woods Hole*, 21 (1911), No. 2, pp. 104-112).—This reports data of experiments with hybrid rats in which the excess of males was so far beyond the limits of normal variation that it appears that hybridizing altered the sex ratio to an appreciable extent. This is in agreement with the results obtained by other observers.

Studies in the experimental analysis of sex.—IX, On spermatogenesis and the formation of giant spermatozoa in hybrid pigeons, G. SMITH (*Quart. Jour. Micros. Sci., n. ser.*, 53 (1912), No. 229, pp. 159-170, pl. 1).—These are studies of normal male pigeons and doves and 3 male hybrids produced by the mating of a male pigeon with a female domestic dove. As a rule the findings of Guyer<sup>b</sup> were confirmed. The following conclusions were drawn:

"The ripe spermatozoa of the hybrids, which were present in large quantities, besides showing in certain cases structural abnormalities, were on the average twice as large as the normal spermatozoa of either parental type.

<sup>a</sup> Phil. Trans. Roy. Soc. London, Ser. A, 194 (1900), pp. 257-319.

<sup>b</sup> Diss., Univ. Chicago, 1900; *Biol. Bul.*, 16 (1909), p. 193; *Anat. Anz.*, 34 (1909), p. 502, 573.

"The first maturation or reduction division in the hybrids is abnormal, in that the chromosomes do not enter into the normal synapse to produce S synaptic or bivalent chromosomes, but they are scattered as irregular chromatic masses of unequal size on the mitotic spindle, and are irregularly distributed to the opposite poles of the spindle.

"The second maturation division in the hybrids is almost entirely suppressed, the secondary spermatocytes proceeding without further division to form spermatids and spermatozoa of twice the normal size. Many of these spermatozoa are structurally normal, apart from their double size, while others are abnormally twisted or beaded. All the spermatozoa were probably impotent, since these hybrids and all others of a similar kind are invariably sterile.

"The explanation of the sterility of such hybrids is found, in accordance with Guyer's idea, to reside in the disturbance of the synaptic division during maturation, this disturbance being due to the incapability of the chromosomes derived from the specifically different parents to fuse to form the normal synapses."

The male generative cycle in the hedgehog; with experiments on the functional correlation between the essential and accessory sexual organs, F. H. A. MARSHALL (*Jour. Physiol.*, 43 (1912), No. 3-4, pp. 246-259).—Recent studies of the sex glands of the hedgehog, combined with previous investigations of other animals, led the author to the following conclusions:

"The males of most, if not all, wild mammals experience a definite sexual cycle, the testes and accessory generative organs passing through alternate periods of rest and activity, but in the domesticated varieties and in man the period of rest is liable to be much reduced or may be absent altogether. . . . The vesiculæ seminales are secretory glands, and do not contain spermatozoa either in the breeding or in the nonbreeding season. Complete castration during the period of rest prevents the seasonal development of the vesiculæ seminales and other accessory male organs, or, if such development has already begun, arrests its further progress. Unilateral castration, however, does not inhibit the growth of the accessory organs and has no effect on the symmetrical arrangement of these organs. Vasectomy, either unilateral or double, does not inhibit the growth of the vesiculæ seminales or other accessory organs, but unilateral vasectomy may prevent the full development of the testis on the side of the operation, as compared in size with the testis on the unoperated side. The periodic development of the accessory organs is not due to stimuli set up by sperm ejaculation, but is probably the result of an internal testicular secretion elaborated in the interstitial tissue during the season of generative activity."

The maturation divisions of the mammalian ovum, M. ATHIAS (*Arch. R. Inst. Bact. Camara Pestana*, 3 (1912), No. 3, pp. 287-370, pls. 4).—A study on the segmentation of the ovum in the cat, rat, mouse, and other small mammals. A bibliography is appended.

Development of new feathers, FRIEDA BORNSTEIN (*Arch. Naturgesch.*, 77 (1911), I, Sup. 4, pp. 1-11, pls. 2; abs. in *Jour. Roy. Micros. Soc.* [London], 1912, No. 3, p. 299).—This is a study of the histology of the feather in young ducks, pigeons, and other birds.

"A new germ is always formed for a new feather; the new germ arises while the old feather is still growing; it is formed from the malpighian layer, at one side of the base of the feather follicle. The new feather germ forms a process which grows into the deeper layers of the cutis, and from this process the new papilla is formed. The old papilla atrophies after the old feather falls off. A study of the foot of the capercaillie, where feathers and scales occur in close

association, led to the conclusion that a feather corresponds not to an entire scale but only to part of a scale, the rest being suppressed."

A bibliography is appended.

**Hard tendons of birds**, E. RETTERER and A. LELIÈVRE (*Compt. Rend. Soc. Biol. [Paris]*, 71 (1911), No. 35, pp. 596-599; *abs. in Jour. Roy. Micros. Soc., [London]*, 1912, No. 3, p. 303).—The so-called "ossified" tendons in birds were found to be due to hypertrophied tendinous tissue, the cells becoming vesicular and the fibers calcified. Around the vascular canals there is a delicate zone of vesicular cells, which take on the characters of true bony tissue.

**The psychological basis of domestication**, P. HACHET-SOUPLET (*Rev. Sci. [Paris]*, 50 (1912), II, No. 10, pp. 293-299).—A study of the domestication of wild animals and birds from the psychological standpoint. The author advocates the establishment of a central institution for domesticating game birds for the purpose of replenishing the farms, fields, and forests of France with new species.

**Stock breeding in the Catanduanes Islands**, E. H. KOERT (*Philippine Agr. Rer. [English Ed.]*, 5 (1912), No. 6, pp. 305-308, pl. 1).—This contains brief notes on the carabao, Catanduanes pony, goats, swine, and native cattle of the Catanduanes Islands.

**Cattle business in Paraguay**, C. FERRIS, JR. (*Daily Cons. and Trade Rpts. [U. S.]*, 15 (1912), No. 181, pp. 586, 587).—This contains information on general conditions of cattle raising in Paraguay.

**Origin and descent of the Norwegian breeds of cattle**, J. FROST (*Amer. Breeders Mag.*, 3 (1912), No. 3, pp. 216-221).—A translation of an article previously noted (E. S. R., 27, p. 277).

**Transmission of color and color markings in Hereford-Shorthorn crosses**, P. E. FOGLE (*Amer. Breeders Mag.*, 3 (1912), No. 3, pp. 201-204).—A progress report by a committee on animal hybrids of the American Breeders' Association.

Among the facts regarding the transmission of color and color markings which are regarded as well founded are the following: "The circle around the eyes would seem to go with the solid red color, as the greater number of red calves carry the characteristic eye circle. The fact that out of 16 roan calves 15 have no red markings on face (having only imperfect eye circles) strongly points to the dissociation of eye circles with roan color. The cross of red and white results in roan, and the roan cow, having received red from one parent and white from the other, transmits the red to about half her offspring and roan to the other half, so that about half the calves from a roan cow bred to a Hereford bull will be red and the other half roan."

**British breeds of sheep**, R. WALLACE (*Pastoralists' Rev.*, 21 (1911), Nos. 8, pp. 841, 842; 9, pp. 952-954; 21 (1912), Nos. 11, pp. 1160, 1161, figs. 8; 12, pp. 1320, 1321, figs. 2).—An account of the origin and characteristics of the following breeds of sheep: Cheviot, English Leicester, Border Leicester, Wensleydale Longwool, Lincoln, Kent or Romney Marsh, Devon Longwool, South Devon, Cotswold, Roscommon Longwool, Dorset Horn, and Ryeland.

**Concerning the fat-tail and the broad-tail sheep**, C. C. YOUNG (*Amer. Breeders Mag.*, 3 (1912), No. 3, pp. 181-200, figs. 9).—This describes the characteristics of the breeds of sheep which have originated from the 2 species *Ovis scotopyga* (fat-tail), and *O. platyura* (broad-tail). See also a previous note (E. S. R., 25, p. 675).

**Monograph on the vicuña**, C. G. MADUEÑO (*Trab. 4. Cong. Cient. Santiago de Chile*, 2 (1908-9), pp. 5-30, pls. 2, figs. 5).—This contains an account of the

history, characteristics, and value for agriculture of the vicuña, which has previously, in the opinion of the author, been underestimated.

Experiments in swine feeding, G. E. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 37 (1911), p. 150*).—A brief report of progress in swine feeding tests.

Skim milk at 20 cts. per hundredweight proved a cheaper source of protein than oil cake at \$36 per ton, but in the absence of skim milk the latter may constitute 10 per cent of the total meal ration. The use of low-grade flours for pig feeding was unprofitable. The amount of water supplied to pigs is thought to be an important factor in growth. The best results were obtained by mixing the meal with enough water to make a thick slop.

Horses and practical horse keeping, F. T. BARTON (*London [1912], pp. 613, pls. 47, figs. 23*).—A practical handbook on the horse dealing with breeds, breaking, management, lameness, diseases, etc.

The horse and its relatives, R. LYDEKKER (*London, 1912, pp. XII+286, pls. 24, figs. 11*).—An account of the natural history of the horse, mule, ass, kiang, and zebra, and their extinct forerunners. The work was written for breeders, racing men, antiquarians, naturalists, and big-game hunters.

Horse breeding (*London: Board of Agriculture and Fisheries, 1912, pp. 69*).—This is the preliminary report of the Animals Division as to the administration of the grant under the Development Act for the encouragement and improvement of the light horse breeding industry.

A history of the Arabian horse and its influence on modern breeds, F. KNORR (*Amer. Breeders Mag., 3 (1912), No. 3, pp. 174-180, figs. 3*).—A brief historical survey.

The evolution of a type of horse, W. S. ANDERSON (*Amer. Breeders Mag., 3 (1912), No. 3, pp. 209-216, figs. 2*).—A discussion of how a type of saddle-horse has been developed by the elimination of undesirable unit characters. The following working hypothesis is suggested:

"The unit characters of the horse may, in a tentative way, be stated to be as follows: That the finer qualities are recessive to the coarse ones; as the thin, pointed ear is recessive to the heavy thick one; the clean, small head recessive to its opposite; the short neck recessive to the long one; the flat foot recessive to the 'mule' foot; the calf knee dominant to the straight, perfect knee; strength dominant to weakness; true action and superior action recessive to untrue and inferior action. In color, chestnut is recessive to gray, bay, and black."

Mendelian experiments with Thoroughbred horses, C. C. HURST (*Bloodstock Breeders' Rev., 1 (1912), No. 2, pp. 86-90*).—An outline of an experiment recently undertaken to produce from Thoroughbreds a race of steeplechasers which will breed true.

The other side of the question (*Bloodstock Breeders' Rev., 1 (1912), No. 2, pp. 90-92*).—A criticism of the above, mainly on the ground that there is no such thing as a Mendelian factor for jumping.

The figure fallacy (*Bloodstock Breeders' Rev., 1 (1912), No. 1, pp. 37-40*).—The weak points in breeding horses by the Bruce-Lowe figure system are pointed out.

Tests of grain and hay for work horses, H. J. WATERS (*Breeder's Gaz., 61 (1912), No. 13, pp. 763, 764, fig. 1*).—These tests were made with artillery horses at the Fort Riley military reservation. There were 10 lots with about 75 in each lot, and 7 lots containing from 17 to 20 horses each. Most of the experiments lasted from 110 to 140 days each.

The cheapest ration, and the one which gave the largest gains, consisted of 8 lbs. of corn, 2 lbs. of oats, and 10 lbs. of alfalfa hay, and cost 13 cts. per

head per day. The gain made was 25.6 lbs. per horse in 140 days. A ration consisting of oats, corn, wheat bran, and timothy hay in the ratio of 4:6:4:12 produced 6 lbs. of gain in 120 days, and the animals showed the best condition of any in the test, but the ration cost 19 cts. per day. When oil meal was used to replace a portion of more expensive grain at the rate of about 1 lb. per day the horses showed excellent condition and there was no evidence of softness. This cheapened the ration about 2 cts. per day over the ration previously used.

[Report of] the professor of poultry husbandry, W. R. GRAHAM (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 37 (1911), pp. 159-167*).—During the year 23 bred-to-lay Barred Plymouth Rock pullets laid 3,514 eggs, as compared with 2,482 laid by exhibition pullets. The latter ate more feed but were larger birds. Data on economic egg production of 341 fowls for 11 months are summarized in the following table:

*Egg record of hens and pullets from October 1, 1910, to September 1, 1911.*

Breed.	Males.	Females.	Eggs laid.	Cost.	Average eggs per hen.	Grain consumed.	Milk consumed.
						<i>Lbs.</i>	<i>Lbs.</i>
Yearling Barred Rocks.....	2	55	5,961	\$73.04	108.38	4,357.0	4,787.0
Barred Rock pullets.....	4	92	11,928	121.32	129.65	2,042.5	9,195.0
Buff Orpington pullets.....	5	60	6,401	69.45	136.68	4,805.0	4,597.0
White Leghorn pullets.....	6	111	13,504	116.32	121.65	6,739.0	8,704.0
Minorea hens and pullets.....	2	23	1,726	31.76	75.04	1,874.0	2,117.5
	19	341	39,520	411.89	115.83	24,817.5	29,400.5

The following table summarizes the effects of different animal feeds in a mixed ration upon egg production. Each lot consisted of 25 females and 2 males.

*Feeding tests with Buff Orpingtons from October 1, 1909, to April 30, 1910, and with Rhode Island Reds from October 1, 1910, to May 31, 1911.*

Kind of animal feed.	Buff Orpingtons.					Rhode Island Reds.				
	Animal feed.	Cost of total ration.	Eggs laid.	Cost per dozen eggs.	Percentage of eggs hatched.	Animal feed.	Cost of total ration.	Eggs laid.	Cost per dozen eggs.	Percentage of eggs hatched.
Buttermilk.....	<i>Lbs.</i> 1,453.00	\$18.16	2,040	<i>Cents.</i> 10.68	55.00	<i>Lbs.</i> 1,760.50	\$25.60	1,762	<i>Cents.</i> 17.43	57.00
10 per cent dry mash beef serap.	34.00	19.85	1,670	14.28	50.50	61.50	23.06	1,320	20.96	56.40
Beef serap in hopper.....	141.00	22.21	1,664	15.84	33.00	106.00	23.92	1,625	17.66	51.60

No animal food.....		17.99	1,496	15.48	59.50		17.70	730	29.09	66.25

The average cost of feed for 100 hens kept in an open house was 16.5 cts. per dozen. In a feeding test which involved 583 chickens, kept in colony houses on a ration of mixed grain and buttermilk, 3.3 lbs. of grain was required to produce 1 lb. of growth.

**Essentials in profitable egg production,** H. R. LEWIS (*New Jersey Stas. Bul. 244, pp. 5-36, pls. 10*).—A bulletin on practical poultry keeping, in which the chief factors concerned in the profitable production of eggs are discussed, and directions given for the hatching, brooding, and feeding of poultry, the marketing of eggs, and poultry house and appliance construction.

**Increasing the egg supply on the farm,** J. B. MORMAN (*Farm and Fireside, 35 (1912), No. 26, p. 4*).—The author gives the egg records of his flock of about

50 laying White Plymouth Rock hens for the 5 years 1907 to 1911, inclusive. By means of charts he indicates how, by the selection and breeding of early and good layers, he has increased the egg production of his flock from 3,966 eggs in 1907 to 5,573 eggs in 1911.

**Increasing the winter yield of eggs, W. T. WITTMAN** (*Penn. Dept. Agr. Bul.* 219, 1912, pp. 91, pls. 20).—This treats in a popular and practical way of the subjects of poultry breeding, management, incubation and brooding, feeds and feeding, houses and yards, and table eggs and egg yield.

**The growth of ducks on four different kinds of feed, A. MAGNAN** (*Compt. Rend. Acad. Sci. [Paris], 154 (1912), Nos. 23, pp. 1535-1538; 25, pp. 1714-1717; 155 (1912), No. 2, pp. 182-184*).—Rouen ducks made a less rapid growth on a vegetable diet than on a diet of either flesh, fish, or insects. The greatest final weights were obtained on the flesh diet. Growth seemed to be arrested more quickly on the fish and insect than on the vegetable diet. Those fed vegetables laid fewer eggs, but the color of the yolk was of a deeper yellow than the eggs of the other lots. The liver and kidneys of the slaughtered lots were larger than where the feed consisted of fish and insects.

**The turkey as an egg producer, W. N. IRWIN** (*Amer. Breeders Mag.*, 3 (1912), No. 3, pp. 204-208, figs. 4).—Attention is called to the value of the turkey as an economical producer of eggs, a feature of the poultry industry which has previously been overlooked.

**Partridges and partridge manors, A. MAXWELL** (*London, 1911, pp. XII+327, pls. 16, figs. 8*).—A popular work in which the partridge is treated as a valuable by-product of the English farm.

**Fur farming for profit** (*New York, 1912, pp. 188, figs. 50*).—"A practical text-book on breeding fur-bearing animals, either as a distinct industry or in connection with specialized or general farming."

**Oyster culture studies in 1910, J. NELSON** (*New Jersey Stas. Rpt. 1910, pp. 185-218, pls. 2*).—The spatting observations were continued in 1910 as in previous years, but the season was unusual in several respects. The fry in the water appeared and disappeared in a more erratic way than usual. There was a large amount of spawn in the oysters, but it was given out grudgingly though at frequent intervals, and the fry so prepared seemed to disappear without setting. Spatting did not take place before June 28 nor after July 7, and the climax occurred in the middle of the first week in July. At that time there was not a large amount of fry in the water. The nearer the shells were planted to the day of the spatting climax, the better the catch. Shells planted June 20 bore an average of 3 spat per shell, those planted June 26, 13, those planted July 1, 14, while those planted on the day of the climax bore more than twice as many. Therefore, even a few days' sojourn of the shells in water was sufficient to deteriorate the spat-catching qualities of the cultch.

The floating laboratory used in this work is illustrated and described. Experiments made in floating oysters are noted on page 762.

**Concentrated feeding stuffs, C. S. CATHCART ET AL.** (*New Jersey Stas. Bul.* 243, pp. 3-62).—This contains the results of feeding stuffs inspection in accordance with the state law and other data. Analyses are reported of cottonseed meal, cottonseed feed, linseed meal, ground flaxseed, flaxseed screenings, gluten feed, hominy meal, distillers' dried grains, meat meal, beef scraps, blood meal, malt sprouts, rye bran, rye middlings, ground rye, ground oats, crushed oats, oat hulls, brewers' dried grains, molasses feed, ground wheat, shredded wheat, wheat bran, wheat middlings, barley blowings, alfalfa meal, dried beet pulp, red dog flour, puffed rice screenings, corn meal, corn-and-cob meal, cob meal, buckwheat middlings, buckwheat bran, buckwheat offal, and proprietary mixed feeds.

**Cattle feeds, R. HARCOURT** (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 37* (1911), pp. 69-71).—Analyses are reported of soy beans, cotton-seed meal, dried brewers' grains, shorts, middlings, a proprietary hog feed, linseed cake, pea meal, apple pomace, and silage.

**The coming of dried beet pulp, D. J. WHITNEY** (*Pacific Rural Press, 84* (1912), No. 3, pp. 49, 62, 63).—Attention is called to the value of beet pulp as a feed for live stock, and particularly the dried pulp which is being produced in increasing quantity in this country.

**Potato greens as stock food, W. DAWSON, JR.** (*Daily Cons. and Trade Rpts. [U. S.], 15* (1912), No. 218, p. 1392).—According to a German authority, the usual general reports, potato tops are not harmful to animals as is commonly supposed. It is believed that the apparatus used for drying beets, potatoes, and other products can be used for drying the potato tops.

**Hides and skins (Chicago, 1912, pp. 15+247, pls. 11, figs. 14).**—This book gives instructions for handling hides of the larger domesticated animals, from the animal's back to the tannery door. It was written mainly for farmers and local butchers. It is stated that hides from Chicago packers bring higher prices than those of the same grade of animals from sources where the hide is not properly handled.

**Regulations for animals on the German railways (Zentralbl. Preuss. Landw. Kammer, 2** (1912), No. 16, p. 111; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intell. and Plant Diseases, 3* (1912), No. 6, p. 136).

—These regulations relate to the care and feeding of animals during transportation on German railways, which were to take effect May 1, 1912.

## DAIRY FARMING—DAIRYING.

**A study of the metabolism and physiological effects of certain phosphorus compounds with milch cows, II, A. R. ROSE.** (*New York State Sta. Tech. Bul. 20, pp. 3-32, figs. 4*).—The work reported in this bulletin was made in order to check the results of work previously noted (E. S. R., 18, p. 568), repeating the work in such a way as to eliminate more of the variable factors. This was effected by adjusting one of the animals used in the previous experiment to a low phosphorus ration, very nearly identical to the one formerly employed, and adding thereto the calcium salt of phytin. The technic of the work differed in no essential way from the previous experiment.

The results are summarized as follows:

"In this, as in the former experiments, the organic phosphorus ingested was eliminated very largely in the form of inorganic phosphorus by way of the intestine, the amounts of phosphorus in the urine being very small. When phytin was withdrawn from the ration, the decrease of phosphorus in the urine was immediate; when phytin was added, a rise in phosphorus occurred after a lag of 2 days. Phytin caused more phosphorus to be eliminated through the kidney than did whole wheat bran. The long duration of the low-phosphorus period did not in itself affect the phosphorus content of the urine nor the phosphorus balance.

"The insoluble phosphorus of the feces diminished with decreasing amounts of insoluble phosphorus in the rations, when the latter ranged above 14 gms.

"The soluble organic phosphorus disappeared very largely from the alimentary tract. The apparent utilization was poorer in the low-phosphorus periods and in the calcium phytate period than in the whole-bran period.

"For maintenance of phosphorus equilibrium in this species of animal the requirement would seem to be the amount of phosphorus eliminated in the milk plus 26 mg. per kilogram of body weight; an excess over this amount causes

phosphorus retention, and smaller quantities result in loss of phosphorus from the organism.

"The addition of calcium phytate increased the potassium both in the urine and dung, and changed the path of elimination of part of the magnesium from the kidney to the intestine. The calcium added as calcium phytate was almost entirely eliminated by the intestine immediately after administration. The calcium of the urine increased with decreasing phosphorus in the rations and decreased when calcium phytate was added.

"The nitrogen compounds of the ration were well utilized and for the most part a positive nitrogen balance was maintained. The animal gained 19 kg. during the experiment, half of which could be accounted for by the plus balance of nitrogen. There was a suggestion of a parallelism between the nitrogen and phosphorus balances.

"The former observations as to the influence of phosphorus compounds on the oestrum and the amount of urine voided were not corroborated; neither was the laxative effect previously noted. The difference in the moisture content of the feces of the several periods of this experiment was very small.

"A long low-phosphorus period resulted in unfavorable symptoms. The animal returned to a normal condition after a week's feeding on ash-rich rations including alfalfa, silage and wheat bran.

"The volume of the milk fluctuated inversely with the amount of phytin phosphorus in the rations. The increase of milk flow on removal of phytin was not a mere dilution. Except for the change in the amount of fat, the composition of the milk was not materially altered. The responses of the fat to the fluctuations of phytin phosphorus were immediate and consistent, as distinct, though not quite as large, as in the previous experiments. The best milk flow, both as to amount and fat content, happened to occur in the period of phosphorus equilibrium."

[Report of] the professor of animal husbandry, G. E. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 37 (1911), pp. 141-149*).—The records of the dairy herd are given and several feeding tests are reported.

When dried brewers' grains were substituted for bran the milk production was increased in 9 out of 11 cows. Cotton-seed meal appeared to be equal to twice its weight of bran. Soy-bean meal gave results almost identical with those from cotton-seed meal. The normal milk yield was retained when a good quality of alfalfa hay replaced the grain ration.

The dairy herd, F. C. MINKLER (*New Jersey Stat. Rpt. 1910, pp. 58-67, pls. 7*).—This gives the individual milk records, and an account of the methods of feeding the college herd. Thirty-one cows gave an average annual yield of 8,661 lbs. of milk with a fat content of 3.96 per cent. The following table gives some of the results obtained with the cows of different breeds kept in the college herd:

*Comparison of the milk yields and income from dairy cows.*

Breed.	Number of cows.	Average yield of milk.	Average fat test.	Average yield of milk fat.	Average yield of milk per day (for entire year).	Average number of days in milk.	Value of milk at 6 cts. per quart.
		<i>Lbs.</i>	<i>Per cent.</i>	<i>Lbs.</i>	<i>Lbs.</i>		
Holstein.....	16	9,724.2	3.43	333.91	26.6	284	\$271.88
Jersey.....	7	7,978.0	5.17	411.84	21.9	293	223.06
Guernsey.....	4	5,822.0	4.85	282.42	15.9	212	162.78
Ayrshire.....	4	8,630.3	3.72	34.43	23.6	270	241.30

[Report of] the professor of dairy husbandry, H. H. DEAN (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 37 (1911), pp. 89-140*).—The value of boric acid, borax, and sodium benzoate were tested as preservatives for Camembert and cream cheese, but they were found unsatisfactory, even aside from the question of healthfulness.

Studies of the effect of keeping soft cheeses at different temperatures gave the following results: "The Camembert cheese kept in the house refrigerator were unsaleable in about a week or 10 days, while the cream cheese remained good for 10 to 12 days under similar conditions. In the ice-cold storage all the cheese kept in first-class condition for about 2 weeks, but they tended to become moldy and go off in flavor after 2 weeks. Where the cheese were placed in mechanical storage at a temperature of 3° below freezing point, the cheese kept well for 3 weeks and were in fairly good condition at the end of nearly a month. Those cheese kept at ordinary room temperature began to go off in flavor and become moldy in about 5 days."

An unsuccessful attempt was made to ripen Camembert cheese, but a Pont L'Eveque cheese was ripened with good results.

In coloring cheese the best results were obtained by using 20 cc. of cheese annatto coloring per 100 lbs. of cream for cream cheese, and 10 cc. per 100 lbs. of mixed milk and cream for the Gervais cheese. Analyses of Gervais, Camembert, and cream cheese are reported.

In experimental work in making Devonshire cream a product of good quality was produced, either by separating the milk with a cream separator at temperature of from 170 to 180° F., or by separating at about 100° and afterwards heating the cream at a higher temperature. It may then be bottled while hot, covered, and set in a refrigerator to cool. Such cream should test from 50 to 60 per cent fat, and should keep in good condition for a week or 10 days. There was found to be less loss of fat than in the ordinary method of setting.

A number of tests were made to compare single-service paper bottles with glass bottles. The milk was pasteurized, then cooled to about 58°, and placed in the various packages and allowed to stand in a room where the temperature averaged 56° F. There was very little difference in the milk in the various containers as to temperature or acidity, but some of the paper packages imparted a package flavor to the milk after standing in them for about 24 hours. One or 2 of the monoservice paper bottles compared favorably with milk in the glass bottles. "If these packages can be put on the market in Canada at a reasonable price, we see no reason why they may not displace the ordinary glass bottle as a container for retail milk and cream."

As a result of experiments in weighing vs. measuring cream samples for Babcock test, the use of a sensitive balance is advised, but where none of the cream tests over 25 to 30 per cent no serious error should result by using an 18 cc. pipette, if care be taken to rinse all the cream from the pipette into the test bottle. No appreciable difference was found in the reading of 3 types of cream scales. In comparing the weights of cream and percentage of fat, no difference was found between the first and the twelfth bottle on the 12-bottle scale.

Numerous tests were made in sampling and testing cream. A sample of cream kept one month in tightly stoppered bottles averaged practically the same percentage of fat whether kept at low temperature or moderately warm temperature. There did not seem to be any advantage in the aliquot method over the uniform sampling for composite testing of cream. After testing numerous preservatives, it was found that the one used at the station for a number of years was as good as any, namely, 3 parts of bichromate of potash and 1 part of corrosive sublimate. The total difference in pounds of fat

credited to 3 creamery patrons' deliveries for the season was 5.195 less on weekly composite tests, as compared with daily tests; 16.602 lbs. less by the semimonthly; and 12.205 lbs. less by the monthly composite test. All of these are considered to be within the limits of error.

There was no difference in temperature and acidity of cream whether kept in a well-glazed crock or in one that was chipped and cracked, but cream kept in the crock in every case had a bad aroma after from 44 to 52 hours. There was but little difference whether or not the cream was cooled before placing in a can or crock, or whether covered or uncovered, in a reasonably clean, cool cellar, although it is stated that further tests are needed. There was but little difference between a covered and open can as against the covered and open crock for holding cream in the cellar. The weight of evidence appeared to favor not covering the cream can or crock provided that the cellar air is pure and free from undesirable odors. In collecting cream in an ordinary milk can and in a wooden-jacketed can, the cream in the latter arrived at an average of 3.4° cooler than did the cream in the milk can, and with slightly less acidity.

The cost of pasteurizing cream for butter making was found to be a trifle over 3 cts. per 100 lbs. of butter. Powdered milk was found to be satisfactory in the preparation of cultures for ripening cream for butter making. Sodium carbonate, sodium bicarbonate, and lime were used as neutralizers for lowering the percentage of acidity in cream, and all produced a marked effect. Pasteurizing further reduced the acidity. "In all cases, except the one where washing soda was used, the cream churned in less time after partial neutralization of the acid before pasteurizing. To some extent this may have been due to less weight of cream in the churn for these lots. There was also a tendency for less loss of fat in the buttermilk from these lots, as compared with the normal lots. There was a little difference in the percentage of moisture and salt in the finished butter from the various lots. The 'overrun' was less in the lots where the cream was neutralized, as compared with the 'overrun' from similar lots not neutralized. In the 4 tests which are comparable, the average 'overrun' in the normal lots was 16.9 per cent, while the others averaged 13.2 per cent. The tendency was for a lower yield of butter in the lots where the cream was neutralized before pasteurizing. There was little or no difference in the average scores for flavor, or in the total scores of the 4 lots. The results by neutralizing with limewater before and after pasteurization of the cream were not decisive. More experiments on all these points are needed before drawing conclusions."

Experiments in pasteurizing resulted as follows: "The pasteurized cream churned at the same temperature, in less time, in all of the comparative tests with raw cream, except at 175° F., where the average time for churning was the same for the pasteurized and raw lots. There was not much difference in the percentage of fat in the buttermilks from the various lots, what difference there was being in favor of the raw cream lots. The percentage of overrun was slightly in favor of the unpasteurized lots. There was not much difference in the quality of the butter except in the lots heated at 175° F., which scored an average of nearly one point higher as compared with lots made from similar cream churned raw."

Various preservatives other than salt, used in butter making, were found to contain from 15 to 38 per cent of sodium chlorid. Butter churned to the size of wheat and corn granules contained more moisture and less salt than similar butters churned to the size of apples. Salt applied in wet form (2 lbs. of water to 5 lbs. of salt) caused a higher percentage of both moisture and salt to be retained in the finished butter.

The casein and cheese investigations were continued along the lines of previous years. The Holsteins produced the most milk, milk fat, and casein; the Ayrshires were second in the amount of milk and casein; and the Jerseys second in the amount of milk fat. The Jersey milk contained the highest percentages of fat and casein. "The single tests of casein in patrons' milk at 10 factories varied from 1.84 to 2.67 per cent. . . . The percentage of fat in the milk at western Ontario factories averaged 3.42, and for eastern Ontario 3.44. . . . The composite sampling for casein was not satisfactory—the tendency being for tests at too high, using the Hart casein tester. Milk ought to be tested at cheese factories, and be paid for on the fat-casein basis. In the meantime 'fat+2' is near enough for all practical purposes, and represents fairly close the available casein and fat in milk for cheese making."

Seasonal tests of fat in casein are also given. "The milks with the higher percentages of casein and fat, produced an average of 6.4 lbs. more cheese per 1,000 lbs. milk, as compared with the lots having lower casein and fat. (Last year it was 4.64.) The yields of cheese per pound of fat and casein were 1.59 lbs. from the lots with low casein and fat, and 1.571 lbs. from the higher casein and fat content milks." This difference is not sufficient to cause any great error by using the fat-casein method as a basis of payment. The cheese made from the higher fat-casein content milks contained 0.39 per cent more fat but there was little difference in the moisture content.

Curds from eastern Ontario averaged 2.249 per cent more moisture at the time of dipping, 0.574 higher in the green cheese, and practically the same in the cheese 1 month old than did the samples from western Ontario. The cheese lost more moisture when ripened in an ordinary room, at a temperature between 60 and 75° F., than in a room with a fairly uniform temperature of 40°. Most of the loss in moisture in ripening occurred in the rind, or the first quarter of an inch on the surface of the cheese, and during the first week of ripening.

As in the work of previous years there was a decided loss in making Cheddar cheese from overripe milk. In testing the effect of acidity, the yield of cheese was less with a high percentage of acidity in the milk at the time of adding the rennet, but the cheese was of a slightly poorer quality. The result of 2 years' work emphasizes the need of dipping with less than 0.2 per cent of acid. The tests with stirring confirmed the conclusion of the previous year, in that slightly stirring caused about one point higher scoring than where curds were not stirred, and about three-fourths point lower average scoring than with those from curds stirred "dry."

Eleven experiments comparing the effects of salting on the basis of weight of milk with salting based on weight of curd showed but little difference. It is advised that from 2¼ to 2½ lbs. of salt per 100 lbs. of curd be used rather than from 2 to 2¼ lbs., the heaviest salting producing the better flavor. One per cent shrinkage can be saved by placing the cheese within a week in a room at 40° to ripen, as compared with 60 to 75°.

## VETERINARY MEDICINE.

The animal parasites of domestic and useful animals, J. FIEBIGER (*Die tierischen Parasiten der Haus- und Nutztiere. Vienna and Leipsic, 1912, pp. XVI+424, pl. 1, figs. 302*).—This is a text and handbook intended for use by students and veterinarians. The subject is dealt with in a systematic way under the main headings Protozoa, Vermes, and Arthropoda. Systematic lists of (1) the parasites and their hosts, (2) hosts and their parasites, with the part of the body infested, and (3) of such parasites that also attack man, are appended.

**Researches on the spirochetes and related organisms, C. DOBELL** (*Arch. Protistenk.*, 26 (1912), No. 2, pp. 117-240, pls. 5, figs. 3).—"From a comparative study of the spirochetes, bacteria, and Cyanophyceæ, I have reached the following conclusions: The spirochetes may be collected into a single group, which may be called the Spirochaetoidea. The Spirochaetoidea are noncellular organisms (Protista). They undoubtedly belong to the Schizophyta (bacteria+Cyanophyceæ), and not to the Protozoa. Among the Schizophyta, they must be placed in the subdivision bacteria and among the bacteria they probably constitute a group of the same systematic status as the cocci, the bacilli, or the Spirilla. The spirochetes differ from the other bacteria in only one feature—though actively motile, they possess no specialized organs of locomotion. Every other character which they possess is represented in other forms of bacteria.

"The group Spirochaetoidea comprises 4 different sets of organisms, which may be classified in the 4 genera Spirochaeta, Treponema, Cristispira, Saprospira."

A bibliography is appended.

**The separation of protozoan species by means of immunity, A. F. COCA** (*Ztschr. Immunitätsf. u. Expt. Ther.*, 1, Orig., 12 (1912), No. 2, pp. 127-133; *abs. in Zentbl. Biochem. u. Biophys.*, 12 (1912), No. 23, pp. 938, 939).—The results show that the various members of the same group (amoeba) can be differentiated with the specific agglutination and complement fixation reactions.

**The nature of trachoma bodies, S. B. WOLBACH and S. H. MCKEE** (*Jour. Med. Research*, 24 (1911), No. 2, pp. 259-264, pls. 3).—The authors find that trachoma bodies, the discovery of which resulted in the introduction of the new term "Chlamydozoa" for a possibly new group of intracellular protozoa, including the bodies found in variola, vaccinia, scarlet fever, contagious epithelioma of fowls, molluscum contagiosum, rabies, and other diseases of animals, are not specific, nor are they parasitic in nature. "We have come to the conclusion that trachoma bodies are the product of mucus secretion under pathological conditions."

**The filterable viruses, a summary, S. B. WOLBACH** (*Jour. Med. Research*, 27 (1912), No. 1, pp. 1-25).—This is a summarized account in which the author discusses 30 diseases produced by filterable viruses. (See also E. S. R., 27, p. 181.)

**In regard to the action of the barium ions upon the heart, N. WERSCHININ** (*Arch. Expt. Path. u. Pharmakol.*, 66 (1911), No. 3, pp. 191-204; *abs. in Chem. Ztg.*, 36 (1912), No. 15, *Repert.*, p. 73).—Like the substances contained in digitalis the barium ions inhibit systole and diastole. The difference, however, is only a qualitative one and is explained by the slight capacity which the barium ions have for penetrating (from without inward) the walls of a frog's heart. Barium ions can be easily removed from the heart by washing.

**Researches on the poisons produced by *Aspergillus fumigatus*, E. BODIN and C. LENORMAND** (*Ann. Inst. Pasteur*, 26 (1912), No. 5, pp. 371-380).—In continuing investigations with *A. fumigatus* (E. S. R., 18, p. 88), the authors find that instead of a single toxin at least 2 are produced by this fungus. One acts as a convulsivant and is soluble in ether, the other is a depressant, insoluble or slightly soluble in ether and volatile.

**Mortality of stock on mangels, C. ASTON** (*Jour. New Zeal. Dept. Agr.*, 3 (1912), No. 3, pp. 214, 215; *Vet. Jour.*, 68 (1912), No. 445, pp. 425-427).—The author reports briefly on investigations conducted following the loss in August of cattle and pigs which had been fed on mangels. Analyses of these mangels made during September showed the juice to contain 0.06 per cent of nitrogen as nitrites and nitrates. Nitrites were present in traces, a fact which seems

not to have been recorded before in mangels, although mentioned as being found in other plant juices in small amounts. "The amount of nitrogen found is equivalent to 0.43 per cent of potassium nitrate, and a cow eating 60 lbs. of mangel juice would consume 116 gm. (4 oz.) potassium nitrate (mangels contain 95 per cent of juice)."

**Catalase and reductase tests in dairy inspection**, L. A. KLEIN (*Cornell Vet.*, 2 (1912), No. 1, pp. 6-20, fig. 1).—A description and a discussion of the advantages to be derived from the use of these tests in dairy practice. A review of the literature is also given.

**Report of proceedings under the diseases of animal acts for the year 1911**, T. P. GILL (*Dept. Agr. and Tech. Instr. Ireland, Rpt. Diseases Anim., 1911*, pp. 69, pls. 3).—This includes a special report on hog cholera and other diseases of animals in Ireland in 1911, by M. Hedley; and a special report on the transit of animals, by D. S. Prentlee. Statistical data are presented in appendixes.

**Annual report on the civil veterinary department, United Provinces, for the year ending March 31, 1912**, E. W. OLIVER (*Ann. Rpt. Civ. Vet. Dept. United Prov., 1912*, pp. 11+23).—This annual report includes accounts of the occurrence of contagious diseases of animals, breeding operations, etc. Statistical data are appended.

**Toxin formation by the anthrax bacillus**, A. MARXER (*Ztschr. Immunitätsf. u. Expt. Ther., 1. Orig., 13* (1912), No. 4, pp. 309-328).—Asporogenic anthrax bacilli produce a heat-stable endotoxin in large amounts. Spore-forming varieties yield the toxin only in small amounts. By injecting this toxin into animals symptoms are produced which simulate those produced by Friedberger's anaphylatoxin or from an extract of the typhoid bacillus (Aronson's extract). The urine from the animals treated with the endotoxin (and presenting the symptoms of shock) when injected into other subjects produced typical anaphylaxis. Like the endotoxins of some other bacteria the treatment of animals with the endotoxin produces no antitoxin in the blood.

**Ascoli's reaction for diagnosing anthrax**, F. DE GASPERI (*Rev. Gén. Méd. Vet., 18* (1911), No. 214, pp. 553-562).—Attempts to obtain the reaction with the spleens and similar material from animals affected with pseudo-anthrax and specific anthrax serum resulted negatively.

**The detection of anthrax with the precipitin reaction**, W. PFEILER (*Berlin. Tierärztl. Wchnschr., 28* (1912), Nos. 9, pp. 149-151; 10, pp. 167-169).—A critical exposition of the precipitin reaction as applied to the detection of anthrax.

**Diagnosis of anthrax with the aid of the bone marrow**, F. WULFF (*Berlin. Tierärztl. Wchnschr., 28* (1912), No. 24, pp. 421-423).—The bone marrow taken from either the diaphysis or epiphysis can be used for detecting the presence of the anthrax bacillus for the purpose of diagnosing the disease. The method proposed gave positive results in instances where the blood or spleen was negative.

**In regard to the so-called immunization of anthrax bacillus according to Danysz**, W. LÉNÁRD (*Centbl. Bakt. [etc.], 1. Abt., Orig., 60* (1911), No. 6, pp. 527-531).—Anthrax bacilli (Pasteur vaccine), cultivated in arsenic bouillon or rat serum, when subsequently grown on agar appear as a slimy culture containing encapsulated bacilli. The reason for this, in the author's opinion, is that the vaccine originally contains organisms which are capable of forming capsules about themselves. According to this an immunization as expressed by Danysz (*E. S. R.*, 13, p. 92) can not be achieved.

Normal virulent anthrax bacilli, when grown according to the above mentioned methods, show no morphological changes.

**Bacillus bronchisepticus (Bronchicanis); The cause of distemper in dogs and a similar disease in other animals.** N. S. FERRY (*Vet. Jour.*, 68 (1912), No. 445, pp. 376-391, table 1).—This is a general account of the disease in which the author summarizes the present status of our knowledge concerning it, together with a report of investigations conducted in continuance of those previously noted (*E. S. R.*, 25, p. 787).

The infectivity of parts of organs of glandered horses, the complement fixation reaction with guinea pigs, and some curative and immunizing tests, H. MIESSNER (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 64 (1912), *Pestschrift F. Locfler*, pp. 121-151, pl. 1).—Only one-quarter of the guinea pigs infected with pieces of the organs of glandered horses became glandered. According to this, the results obtained with the infection test must be interpreted with care. Guinea pigs infected with defibrinated blood rarely took the disease. Guinea pigs infected with either the organs or blood of glandered animals can only be considered glandered when the findings of the complement fixation test have been confirmed by the autopsical findings or the animals have gone through the course of a light form of the disease during their lifetime. Therefore the complement fixation reaction, when used for diagnosing glanders in guinea pigs, i. e., infection tests, can not be relied upon.

Guinea pigs were treated with mallein or a killed culture of the glanders bacillus for the purpose of determining whether the serum of these animals behaves as does that obtained from horses pretreated in the same way. This was answered in the affirmative with the aid of the complement fixation test. Artificial and natural gastric juice did not seem to have any particular bactericidal action for the glanders bacillus. Glanders bacilli placed directly in the stomach of guinea pigs produced glanders in these animals. Horses which were fed cultures of *Bacillus mallei*, given with the food, did not contract the disease. Immunizing tests with antiformin solutions of the glanders bacillus and guinea pigs showed that a single or a double treatment (given subcutaneously or intra-abdominally) did not produce an immunity in these animals. The salvarsan treatment was not effective for glanders.

**The mallein test and its "vagaries,"** H. G. SIMPSON (*Vet. Rec.*, 24 (1912), No. 1226, pp. 417-430).—In this article are discussed the relation between local and thermal reactions and the number and age of lesions found on post mortem, irregularities of the local manifestation, deferred and double local reaction, "lungers," and the results of a large number of tests and autopsies conducted by the author.

**Leishmaniasis and babesiasis in Yucatan,** H. SEIDELIN (*Ann. Trop. Med. and Par.*, 6 (1912), No. 2, pp. 295-300, fig. 1).—The author states that a cattle importer has estimated that the loss of imported cattle due to splenic fever (piroplasmosis) would reach as high as \$70,000 within a period of 3 months. Native cattle are said to suffer from the disease in a mild form. A chronic case of canine piroplasmosis is reported to have been observed.

**The hemolytic action of mastitis milk,** F. MOSER (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 65 (1912), No. 4-5, pp. 269-296).—The milk from animals affected with mastitis as a rule contains complement, the amount, however, being subject to a great many variations and dependent to quite an extent upon the degree of inflammation. Milk which has a normal appearance contains little or no complement. Hemolytic amboceptor was not noted. The hemolytic method is considered of no value for practical purposes because simpler methods are at our disposal.

**The pathological anatomy of natural and experimental murrina—a trypanosomal disease of the Isthmus of Panama,** S. T. DARLING (*Jour. Med. Research*, 26 (1912), No. 2, pp. 219-247, pls. 2).—In this paper the author reports

studies of the pathological changes elicited in a variety of animals naturally and experimentally infected with *Trypanosoma hippicum*, namely, native horses, American mules and work horses, dogs, raccoons, monkeys, *Cebus hypoleucus*, *Nyctipithecus* sp., rabbits, guinea pigs, rats, mice, and coats.

**Trypanosomes infecting game and domestic stock in the Luangwa Valley, northeastern Rhodesia**, A. KINGHORN and W. YORKE (*Ann. Trop. Med. and Par.*, 6 (1912), No. 3, pp. 301-315).—Trypanosomes are of frequent occurrence in game and domestic stock in the Luangwa Valley. At least 37.5 per cent of the buck harbor parasites. Six species of trypanosomes were found, viz. *Trypanosoma rhodesiense*, *T. vivax*, *T. nanum*, *T. pccorum*, and 2 others, of which one was possibly *T. montgomeryi*.

"*Glossina morsitans* in nature transmits 2 of these trypanosomes, viz. *T. rhodesiense* and *T. pccorum*, and probably also transmits at least 2 others, viz. *T. vivax* and *T. nanum*. Circumstantial evidence exists to show that *T. pccorum* may be transmitted by biting insects other than tsetse flies."

**Serological methods for diagnosing trypanosome diseases**, F. RUPPERT (*Berlin. Tierärztl. Wchenschr.*, 28 (1912), No. 22, pp. 381-383).—This is a study and description of serological methods for diagnosing dourine and nagana with the aid of agglutination, precipitin, the Porges-Meier reactions, and the complement fixation method. Good results were obtained with the first 3 methods, but the tests with the complement fixation method were not conducted under ideal conditions.

**The relation of animal fat to tubercle bacillus fat**, W. C. WHITE and A. M. GAMMON (*Jour. Med. Research*, 26 (1912), No. 2, pp. 257-266).—In this paper the results of a preliminary study of the behavior of various animal and vegetable fats, viz. stearic acid, oleic acid, palmitic acid, linolic and linoleic acid, and butter and human fat with tubercle bacilli growing on glycerin agar, are reported. Olive oil was used as a source for the oleic acid, palm oil for the palmitic acid, linseed oil for linolic and linoleic acids, and beef suet for the stearic acid. On the basis of the results obtained the authors suggest an explanation for the caudal lobe lesions in cattle and the apical lesions in tuberculosis of man, as follows:

The pulmonary artery, before dividing into the right and left pulmonary branches, forms a great bay of blood bounded by a very elastic vessel wall. The blood in this portion of the pulmonary artery must move with comparative slowness, because of the short circuit which it makes in comparison with the long circuit made by the general aortic quota of blood. In this great bay the blood is loaded with fatty derivatives of low specific gravity compared with the whole blood. Owing to the slowness of the current, these compounds have a chance to rise to the surface of the stream, so that the upper layer of blood in the pulmonary artery should have a much larger content of fatty compounds than the lower one. At the highest point of this main blood stream in man the vessel arises that supplies the apex of the upper lobe on either side, so that if the theory advanced be correct, this vessel should be the vessel most laden with the fatty compounds of low specific gravity which are being poured into the pulmonary stream by the liver mechanism. "This view, coupled with the results of our experimental work so far completed, which shows that the tubercle bacillus makes use of these compounds for its more abundant growth, seems a most reasonable explanation of its more prevalent development in the apex of the upper lobe."

**The relations between the human and the bovine type of tubercle bacillus**, G. S. WOODHEAD (*Lancet [London]*, 1912, I, No. 22, pp. 1451-1457).—This is an address delivered at the International Conference of Tuberculosis, held at

Rome in April, 1912. It deals principally with the findings of the British Royal Commission on Tuberculosis (E. S. R., 26, p. 884).

**Human and bovine tuberculosis**, H. VALLÉE (*Rev. Vét. [Toulouse]*, 37 (1912), No. 6, pp. 350, 351).—The author believes that the disease is transmissible from animal (bovine) to man, particularly to infants. The majority of cases in man, however, are deemed due to transmission from man to man.

The relative importance of the human and bovine type of tubercle bacilli for the production of tuberculosis in man, A. CALMETTE (*Rev. Hyg. et Pol. Sanit.*, 34 (1912), No. 4, pp. 349-357).—Repeated contact or infection with large doses of the bovine type of bacillus will produce tuberculosis in man, especially in young children. The greatest source of danger lies in the communication of the disease from man to man. This is shown by the occurrence of pulmonary tuberculosis in countries where no tuberculous cows are present and where no cow's milk is fed to the young.

The complement fixation reaction in tuberculosis, C. HAMMER (*München. Med. Wchenschr.*, 59 (1912), No. 32, pp. 1750-1752; *abs. in Centbl. Bakt. [etc.]*, I. Abt., Ref., 54 (1912), Beiheft, p. 201).—Forty-three out of 46 cases of the disease in man were diagnosed by this method. Of the cases recorded 35 were pulmonary, 7 surgical, 1 glandular, and 3 lupus. In addition to this the test gave positive results in 20 out of 26 cases of suspected tuberculosis in bovines. On autopsy 19 out of the 20 reacting animals showed the lesions of tuberculosis. Some of the lesions were very slight.

The sero diagnosis of bovine tuberculosis, HAMMER (*Deut. Tierärztl. Wchenschr.*, 29 (1912), No. 39, pp. 593-596).—This is a continuation of the work reported in the abstract above and gives in detail the technic used in the experiments and some additional results obtained with 96 bovines.

Of these 96 animals 48 were found to be tuberculous upon slaughter and 48 free from the disease. The complement fixation test with the same lot of animals showed 50 to be tubercular and 46 healthy. The antigen employed was made from a tuberculous peritoneal nodule and old tuberculin.

The cooperative dairy industries in Germany and stamping out tuberculosis according to the new national epizootic law (*Molk. Ztg. Berlin*, 22 (1912), No. 25, pp. 290, 291).—This is a discussion of this law as it applies to the cooperative dairies of Germany. The methods for treating the milk obtained from infected animals, results of the clinical examination of the animals, and notes on their elimination from the herds are also included.

The lymphatic system of the bovine, H. BAUM (*Das Lymphgefässsystem des Rindes. Berlin, 1912, pp. XII+170, pls. 32*).—This work consists of 4 parts. The first or general part (pp. 1-10) deals with technique, terminology, etc.; part 2 (pp. 11-53) with the lymph-nodes; and part 3 (pp. 54-162) with the lymphatic vessels. In part 4 (pp. 163-165) the lymph-nodes and lymphatic vessels of the different parts and regions of the body are brought together. The work is illustrated by colored plates and a bibliography of 60 titles is appended.

The nature of the marginal points occurring in the blood corpuscles of cattle, M. KOIZUMI (*Centbl. Bakt. [etc.]*, I. Abt., Orig., 65 (1912), No. 4-5, pp. 337-340, pl. 1).—Studies of blood smears taken from cattle in the southern part of Formosa, where an endemic disease closely allied to Texas fever is found, have led the author to conclude that it is due to *Babesia (Piroplasma) bigemina*. The marginal points are thought by him to represent a stage of *Babesia*, since they remain for a long time in the blood corpuscles of recovered cattle and serve as a source of infection to new comers.

When cattle are on the way to recovery the marginal points as described by Smith and Kilborne make their appearance in addition to the large forms. For sometime afterwards, both large forms and small bodies are found in vari-

ous proportions. As the animal continues recovering its health, the former become gradually reduced in number until finally the latter only comes to be found in blood. . . . While studying blood smears of cattle in which both the normal forms and the marginal points are found together, I could find several intermediate forms between these 2 and the course of formation of the former from the latter."

The author states that he can not accept the view that all of the marginal points, or coccus-like bodies, are no other than *Anaplasma marginale*. "I can not but believe that *Babesia bigemina* at least, takes a form of the marginal points in its life cycle as believed by Smith and Kilborne, Knuth, Ollwig, and Manteufel. . . . I also had opportunities of examining such forms in blood of calves, mice, and rats. And it was found that they are clearly distinguished from the marginal points appearing in the life cycle of *B. bigemina*."

Some notes and suggestions in connection with the etiology of bovine onchocerciasis, J. B. CLELAND (*Jour. Trop. Med. and Hyg.* [London], 15 (1912), No. 15, pp. 232-235).—A further discussion of the etiology of this disease (E. S. R., 25, p. 887).

It appears most likely that *Stomoxys calcitrans* is the insect host concerned in the transmission of the embryo of this parasite from host to host. Since embryos from the worm nests are occasionally liberated into the blood stream, this fly has an opportunity to imbibe one or more of the sparsely distributed embryos and, after a partial development, to inoculate a fresh vertebrate host therewith.

Streptotrichosis in a bullock in India, G. K. WALKER and R. BRANFORD (*Vet. Jour.*, 68 (1912), No. 47, pp. 541-545, figs. 4).—The author records a case of this disease in a bullock in the Punjab.

Notes on the muscular changes brought about by intermuscular injection of calves with the virus of contagious pleuro-pneumonia, W. H. BOYNTON ([*Philippine*] *Bur. Agr. Bul.* 20, 1912, pp. 10, pls. 4).—"From all appearances the contagious pleuro-pneumonia virus seems to have a specific action upon muscle and connective tissue, affecting chiefly the connective tissue elements. The appearances suggest that the virus multiplies in the lymph spaces of the connective tissue and blood vessels, gradually working its way through the walls of the blood vessels, causing an inflammation of the intima and thus giving rise to thrombus formations. The virus having invaded the tissue gives rise to a serofibrinous exudate, intermingled with groups of leucocytes leading to thrombosis of both lymph and blood vessels.

"The muscle lesions correspond with the lung lesions of contagious pleuro-pneumonia in the following respects: Thrombus formation in the veins in both tissues; the inflammatory areas around the blood vessels are similar; the connective tissue is chiefly affected in both tissues; the abundant sero-fibrinous exudate is present in both; the deep staining line of leucocytes along the edge of the connective tissue is characteristic in both tissues; the tendency toward a chronic productive inflammation is present in both."

A study of the normal blood of the carabao, W. H. BOYNTON ([*Philippine*] *Bur. Agr. Bul.* 21, 1912, pp. 12).—Twenty-five animals in normal condition, from 2½ to 6 years of age, were used in the studies here reported.

"In the circulating blood of supposedly normal carabaos over 2 years old the red corpuscles were found to average 6,057,520 per cubic millimeter. The average percentage of hemoglobin was 92.6. The average number of leucocytes was 10,389 per cubic millimeter. The average specific gravity found was 1.0532. The relative volume of corpuscles to plasma was found to be 29.1 per cent of corpuscles to 70.9 per cent of plasma. The average time for complete coagulation of the blood was found to be 3 minutes and 16 seconds plus."

Of the 5 varieties of leucocytes found in the peripheral blood, 48.5 per cent were lymphocytes, 4.6 per cent large mononuclears, 34.5 per cent polynuclears, 11.5 per cent eosinophiles, and 12 per cent mast cells.

**Contributions to the knowledge of the involution of the normal uterus of the goat.** G. HAENISCH (*Beiträge zur Kenntnis der Involution des normalen Uterus der Ziege. Inaug. Diss., Univ. Leipzig, 1911, pp. 64, pls. 4*).—A report of studies of 32 individuals. A bibliography of 30 titles is appended.

**Notes on the attenuation of virus in the blood of cholera hogs to prepare a vaccine.** R. GRAHAM (*Amer. Vet. Rev., 41 (1912), No. 3, pp. 330-334*).—Tests were made for the purpose of determining the advisability of using hog-cholera vaccines heated to 60° C. for immunizing against this disease.

The results show that the inoculation of a virus attenuated at 60° for 1 hour does not produce a sufficient immunity to protect hogs against this disease. It also usually presents the additional danger of actually producing hog cholera, as was shown in the experiment. The temperature to which the liquid blood must be heated to produce a reliable vaccine is variable, and the same dose of vaccine may kill, protect, or nonprotect, upon inoculating animals of the same size under similar surroundings. Virus attenuated by heating to 60° when not carbolized will remain virulent for at least 24 days.

**Vaccination against hog cholera.** F. S. SCHOENLEBER (*Kansas Sta. Bul. 182, pp. 439-464*).—Of 292,400 hogs vaccinated with the serum produced at the Kansas College during 1911 reports were received in regard to 32,894 head, which had been given the serum treatment alone, the serum-simultaneous method, or the author's combination method, i. e. serum alone followed in 10 days by the serum-simultaneous method, with results as follows:

*General summary of Kansas hog-cholera vaccinations.*

Condition of herd.	Method.	Number of herds.	Number of vaccinations.	Number of deaths.	Number of recoveries.	Percentage of recoveries.
Diseased.....	Serum alone...	235	46,543	5,031	11,506	69.55
Noninfected.....		145	9,350	24	9,326	99.73
Total.....		380	25,893	5,055	20,832	80.50
Diseased.....	Simultaneous.	8	657	52	605	92.00
Noninfected.....		33	2,565	82	2,483	96.80
Total.....		41	3,222	134	3,088	95.50
Diseased.....	Double.....	14	909	388	521	57.30
Noninfected.....		18	2,870	24	2,876	99.17
Total.....		32	3,779	412	3,367	89.00
Diseased.....	All methods...	257	18,109	5,471	12,632	69.80
Noninfected.....		196	14,785	130	14,655	99.10
Total.....		453	32,894	5,601	27,287	83.00

In addition to the above the bulletin discusses in a clear and concise way the 3 methods of vaccinating, the Kansas state law, immediate effects of vaccination, losses, care of hogs before and after vaccinating, instruments, the serum and its production, controlling the disease, when and when not to vaccinate, effect of vaccination on the offspring, stocking up after an outbreak, forms of the disease, conditions favoring the disease, conditions or diseases which resemble cholera, manner of infection, period of incubation, prevention of the disease, disinfection, post mortems, and a few precautions and hints.

**Ascoli's thermoprecipitation reaction as a diagnostic aid for swine erysipelas.** M. IWICKI (*Berlin. Tierärztl. Wchnschr., 28 (1912), No. 23, pp. 401,*

402).—This is a study of the Ascoli method as applied to the diagnosis of erysipelas in hogs. The organs used were the kidney and spleen. In some cases both were employed.

Although a few negative results were obtained with positive material, the author believes that the method can be used providing a specific serum of the proper strength is employed. Special emphasis is placed on the point that some additional work will have to be done in regard to preparing a more suitable serum for this purpose.

**Infection with *Bacillus aerogenes capsulatus*, S. A. DEMING** (*Amer. Jour. Vet. Med.*, 7 (1912), No. 9, pp. 365, 366).—The author reports observations of a case of this infection in the mule in Iowa.

**The condition of the digestive tract in parathyroid tetany in cats and dogs, A. J. CARLSON** (*Amer. Jour. Physiol.*, 30 (1912), No. 4, pp. 309-340).—"There are no spasms, contractures, or other evidence of hyperexcitability or tetany of the neuro-muscular mechanisms of the digestive tract in parathyroid tetany in cats and dogs. Even in very severe tetany the movements of the stomach and the intestines may be normal. The deviation from normal is in the direction of depression or paralysis."

**Observations on fowl and ducks in Uganda with relation to *Trypanosoma gallinarum* and *T. gambiense*, H. L. DUKE** (*Proc. Roy. Soc. [London], Ser. B*, 85 (1912), No. B 580, pp. 378-384, pl. 1).—The author concludes that *T. gallinarum* can multiply in the gut of *Glossina palpalis*, although this fly is probably not the normal host. Muscovite ducks are not thought capable of acting as a reservoir for *T. gambiense*.

## RURAL ENGINEERING.

The storage of water for irrigation purposes.—I, Earth-fill dams and hydraulic-fill dams. II, Timber dams and rock-fill dams, S. FORTNER and F. L. BIXBY (*U. S. Dept. Agr., Office Expt. Stas. Bul.* 249, pts. 1, pp. 95, pts. 20, figs. 41; 2, pp. 64, pts. 8, figs. 38).—Small and medium sized reservoirs are deemed as urgently needed to provide additional water supply for arid lands as are large reservoirs and to have a more extended use, especially in the late summer seasons if the stream flow is short and water is needed for stock and the more valuable crops such as alfalfa, potatoes, sugar beets, sugar cane, and orchards. In this bulletin the types of dams suitable to small reservoirs only are considered. Several different types of these dams and several specific structures with cost data are described, and a large amount of information is given relative to the proper location, construction, and lining of the reservoirs, the different methods of location and design, and the equipment, methods, and material of construction of these dams with spillways, gates, valves, conduits, and all operating machinery.

Tests indicate that in earthen dam construction it is advantageous to use a mixture of materials ranging from fine to coarse to effect as high a degree of compactness as possible, and that the foundation should be on firm and reasonably dry ground. In hydraulic-fill dam construction the features to be considered are a supply of water with a flow of from 2 to 20 cu. ft. per second under a pressure of from 40 to 75 lbs. per square inch; suitable material such as may be readily sluiced into place and will give the required degree of compactness, stability, and imperviousness; and available quantities of this material close enough by to make transportation by the hydraulic method practical. The timber dam is regarded as a suitable and economical structure in all the smaller and less expensive irrigation systems because of its cheapness in first

cost, ease and rapidity of construction, and its adaptability to a wide range of conditions and locations. In rock-fill dams the greater part of the structure consists of loose rock dumped into place and rendered impervious by the use of earth, lumber, concrete, or steel, the size of the dam and the ultimate cost of obtaining and placing the materials determining which is preferable in each case. The mass and weight of the rocks provide the necessary stability against water pressure and overturning and sliding tendencies.

**Shallow pumping for irrigation in the West**, W. L. WILDER (*Mid-Continent*, 5 (1912), No. 7, pp. 14-17, figs. 7).—This general discussion of shallow irrigation pumping in the West indicates that the best sources of cheap power on the farm at the present time are the gasoline engine and the electric motor. To these are considered due the success of shallow irrigation pumping. Several forms of pumps and water-lifting devices in present use are described.

**Irrigation by pumping in western Kansas**, F. D. COBURN (*Topeka, Kans.*, 1912, pp. 12, figs. 3).—The author discusses the possibilities presented by irrigation pumping in western Kansas, describing several private pumping plants in use which give satisfaction and showing that whenever irrigation by pumping from deep bored or artesian wells may be done to supplement rainfall it will bring about great increases in crops.

**A new method of subirrigation** (*Texas Farm Co-operator*, 35 (1912), No. 35, pp. 1, 2).—A description is given of a subirrigation system in Texas in which the water is distributed by concrete pipe, the main pipe, 4 in. in diameter, running the length of a field and feeding 2-in. lateral pipes which are laid at intervals of 33 ft. At intervals of 3 ft. small holes are made in the tops of the lateral pipe in which are inserted small plugs with pin hole end openings. Concrete caps are placed over these plugs, leaving just enough space to allow the water coming through the plug to percolate from under the cap and into the soil. It is claimed that a well with a capacity of only 40 gal. per minute furnishes sufficient water to irrigate 20 acres, using a 4½-in. working barrel pump driven by a 2-horsepower engine. The advantages presented by this system are the great savings of land and water.

**Overhead irrigation in the citrus grove** (*Pacific Rural Press*, 84 (1912), No. 2, p. 28).—A system of overhead irrigation is described in which galvanized iron pipe lines are run underground through every alternate row of trees, and stand pipes 15 ft. high are raised through every fourth tree, the water being distributed through rotary sprinklers. The head pipe is 4 in. in diameter and is tapped by 17 rows of 1½ in. pipe, which reduces to 1¼ in. toward the center and to 1 in. along the lower third. The branch pipes to individual trees are ¾ in. and the stand pipes ⅝ in. The pumping is done by electricity and the cost of the system was about \$150 per acre.

**Super-elevation of water surface in passing around curves at high velocities** (*Engin. and Contract.*, 38 (1912), No. 1, p. 24, figs. 2).—A mathematical discussion is given providing for a raise in the outside walls of irrigation canal curves to prevent loss of water due to superelevation.

**[Duty of water]**, W. W. McLAUGHLIN (*Mid-Continent*, 5 (1912), No. 5, pp. 25, 26, fig. 1).—This is a general discussion of the meaning of the duty of water, presenting the opinion that this should be based entirely upon the economic productive power of the water, including net return on money invested, labor and equipment required, and the marketable qualities of the crop produced, rather than on the amount of water required to produce a certain quantity of crop, and thus distinguishing between primitive methods and modern scientific methods of irrigation.

**Notes on irrigation in Cape Colony**, J. MULLIE (*Bul. Agr. Congo Belge*, 3 (1912), No. 2, pp. 257-290, pl. 1, figs. 25).—A general discussion of the

geography and meteorology of Cape Colony is followed by notes on the cost of irrigation per acre, the value of irrigated lands, surface and subsurface waters, irrigation work, duty of water, and the general extent of irrigation in the colony.

[Practical problems in irrigation, drainage, and hydraulics on the farm], W. B. GREGORY (*Hacienda*, 7 (1912), No. 10, pp. 291-299, figs. 20).—This article deals with irrigation and drainage and general agricultural hydraulics, discussing the selection and installation of power machinery, pumps, etc., for irrigation pumping, the preparation of the soil for irrigation, the amount and frequency of irrigation, drainage of irrigated lands, drainage by hydraulic machinery, and the possibilities of converting hydraulic energy into electrical energy.

Canada's drainage problem, W. H. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 37 (1911), pp. 65, 66, fig. 1).—It is stated in this report that in Ontario as a whole there are from 25,000,000 to 30,000,000 acres of land needing drainage, for much of which large outlets must be provided by the government. The increased crop returns for the entire Dominion following drainage are estimated at several billions of dollars per annum.

Plans for and estimates of costs of draining 33,000 acres of swamp land in North Carolina (*Engin. and Contract.*, 37 (1912), No. 29, pp. 565, 566, figs. 2).—Ten different ditches are included in this work, designed to carry 1 in. run-off per 24 hours with side slopes of 1:1 and a minimum width of 14 ft. The cost of the entire work is estimated at \$142,621, or about \$4.32 per acre.

A good form of tiling contract, F. O. NELSON (*Successful Farming*, 11 (1912), No. 8, p. 18).—A form for contracts between landowner and tiling contractor to be used in all cases, thus eliminating the usual unsatisfactory verbal contract on small tile drainage jobs, is suggested.

[Experimental road work near Baltimore, Md.], W. W. CROSBY (*Good Roads*, n. ser., 4 (1912), No. 10, pp. 93-99, figs. 7).—This is a summary with tables of results and costs of experiments with the penetration method of bituminous road construction. The road is about 6½ miles long and varies from 14 to 24 ft. in width. The old macadam surface was scarified, reshaped, and the foundation strengthened where necessary. It was rolled and covered with a 4 in. layer of 1 to 2 in. crushed stone with a ½ in. per foot crown. This was rolled to the utmost possible compaction and hot pitch applied and evenly distributed. A thin coating of ¼ to 1 in. clean stone chips was placed on top to absorb the excess pitch and fill the extra voids, the quantities of pitch and stone chips varying greatly per square yard under different circumstances. Some sections of the work were made of ordinary water-bound macadam with a top coat of cold pitch and stone chips.

Where the quantity of pitch used was in excess of 1.7 gal. per square yard the bleeding of the pitch in hot weather and the slipperiness in cold weather were found particularly objectionable, especially where tars were used. On the whole, after from 2 to 3 years, the condition of most of the sections is deemed satisfactory, the cost being the only questionable feature.

Road building by convict labor in Colorado, T. J. TYNAN (*Threshermen's Rev.*, 21 (1912), No. 5, pp. 59, 60, 62).—Attention is called to the use of convict labor in Colorado for road building, as being much cheaper than other labor. It is noted that 50 miles of rock road were constructed at a cost of \$1,134 per mile, which by ordinary labor would have cost \$25,000 per mile.

Concrete roads in the country, N. A. CLAPP (*Farmers' Rev.*, 44 (1912), No. 20, p. 532, figs. 3).—Attention is called to the progress of concrete road construction in Wayne County, Mich., briefly reviewing methods of construction

and noting the commercial and social advancement of the community. The cost of these roads is about \$16,000 per mile.

An act creating a state highway department and providing aid in construction and maintenance of highways (*Ohio Highway Dept. Bul. 14, 1911, pp. 19*).

[Reducing the cost of farm power], D. C. SHAFER (*Tribune Farmer* [N. Y.], 11 (1912), No. 561, pp. 1, 2, 21, figs. 4).—This article enumerates as the 3 reliable sources of farm power internal combustion engines, electricity, and water power, and discusses their use in connection with the heavy work ordinarily performed by men and horses. The fallacy of installing low voltage electric power systems is pointed out and methods of harnessing and transmitting small water power are outlined.

Electricity on the farm, P. A. BATES (*Nat. Land and Irrig. Jour.*, 6 (1912), No. 2, pp. 6-8, figs. 9).—This article deals with the use of electricity for operating cream separators, churns, milking machines, and dairy refrigerators in small farm dairies and describes installations in present use.

The storage battery in isolated lighting plants, T. MILTON (*Gas Engine*, 14 (1912), No. 7, pp. 353-356).—Investigations of the storage battery when used in connection with isolated electric systems indicate that by the use of storage batteries, electric light and power may be had for 24 hours by operating the gas engine and dynamo a much shorter time.

The power windmill and electric lights on the farm, F. FORREST (*Wis. Farmer*, 41 (1912), No. 30, p. 709, fig. 1).—A description of a farm power plant driven by a windmill which operates several machines by belt and shaft drive and also an electric generator for electric light, the entire cost of the plant being about \$250.

[Running and maintenance of the internal combustion engine] (*Gas Engine*, 14 (1912), No. 9, pp. 482-485).—Notes are given on the starting, running, and maintenance of internal combustion engines with directions for maintaining the following conditions on which the good working of the engines depend: Suitability and steady supply of fuel, correct fuel mixture, sufficient compression, correct valve and ignition timing, efficient governing, good water circulation in the jackets, good but not excessive lubrication, and general cleanliness.

Selection and care of gas traction engines and equipment, F. H. CROSSMAN (*Canad. Thresherman and Farmer*, 17 (1912), No. 6, pp. 30, 32).—The author recommends for private work a 15 to 30 horsepower, single cylinder, throttle governed, water-cooled, gas or kerosene engine, and for a general public plowing business a 30 to 60 horsepower, oil-cooled, gas or kerosene engine. He gives brief directions for the care and use of the engine and its equipment, and suggests a list of tools and other handy equipment.

[The gas engine governor], C. W. HULL (*Gas Engine*, 14 (1912), No. 9, pp. 479, 489).—Directions are given for the care of the governing mechanism on internal combustion engines, more especially on the hit-and-miss governed type. It is stated that the speed should be controlled with minimum variation from no load to full load and from full to no load in order to prevent injury to the engine due to sudden speed changes, to obtain the best results from the driven machinery, to give fuel economy, and to save the time wasted by hand regulation.

Some lubrication problems, A. E. POTTER (*Gas Engine*, 14 (1912), No. 7, pp. 343-348).—This is a paper read before the National Gas Engine Association at Milwaukee, in which the author discusses gas engine lubrication. He states that the simplest and easiest gas engine to lubricate efficiently is the horizontal 4-cycle engine, and maintains that every vertical gas engine piston

should have a ring at its lower extremity, in addition to the usual piston rings, to create a pressure to force oil accumulations to the wrist-pin bearings rather than to the combustion chamber. He points out the evils of the splash and flushing systems of lubrication and advocates the automatically regulated pressure pump system used in most foreign designs. He discusses the fire, cold, and viscosity tests of oils, and states that a high-fire test, fairly thin oil is best adapted to vertical engines using a positive force-feed lubrication system, while a low-fire test oil better answers the requirements where splash systems are employed, on account of allowing for a sure sufficiency for a less positive system in order that the excess oil may be more completely consumed in the combustion chamber.

**Cooling the farm engine.** J. H. BEATTIE (*Farm Machinery*, 1912, No. 1072, pp. 15, 16).—Attention is called to the importance of keeping the cylinder of a gasoline engine cool, and several farm engines are described which are cooled by air, water, or oil.

**A gas locomobile.** L. DUBOIS (*Jour. Agr. Prat., n. ser., 23* (1912), No. 21, pp. 654, 655, figs. 2).—A description is given of a power and tractor outfit consisting of a combination of internal combustion engine and gas generating equipment. The engine is a 4-cycle, water cooled type manufactured in sizes of from 8 to 55 horsepower, and burns the gas direct from the attached generator.

**Problem of the small tractor.** L. W. ELLIS (*Farmer's Advocate*, 47 (1912), No. 1032, pp. 960, 961, figs. 4).—This is a paper read before the National Gas Engine Trades Association at Milwaukee.

The author discusses the small tractor problem confronting tractor designers and compares American with foreign design. The French designers have dealt most extensively with small, all-service tractors, and combinations of tractor engine with plowing and cultivating devices, with indifferent success, while the Americans have dealt almost exclusively with large tractors for heavy work. "Practically every idea submitted abroad has been the subject of original investigation and experiments in this country, and actual experience has shown the impracticability of many of what are superficially regarded as essentials of the small tractor."

**Why a kerosene tractor.** R. OLNEY (*Irrig. Age*, 27 (1912), No. 10, pp. 372, 373, figs. 4).—A discussion of the fuel question for internal combustion tractors, giving a comparison of the costs of using gasoline and kerosene in a special type. With this tractor plowing was done with gasoline for 72.6 cts. per acre and with kerosene for 58.6 cts. per acre.

**Can tractor rating be standardized?** (*Canad. Thresherman and Farmer*, 17 (1912), No. 7, pp. 44b, 44c).—A discussion of the problem of a standard system of rating for tractors. One opinion expressed is that since a tractor is required to operate under widely varying conditions of soil, roadway, and weather, a conservative brake horsepower rating of 20 per cent below the possibly developed brake horsepower should be adopted, while another opinion is that a standard method of testing could be adopted requiring the use of a pair of drums mounted on a shaft running on roller bearings and connected to a Prony brake. The tractor should be made to climb planks into such a position that the traction wheels would be in contact with and supported by the drums and held in this position by a draw-bar dynamometer connected to a post. By this apparatus and by scales under the front wheels and the draw-bar dynamometer, the load on the traction wheels when pulling and at rest, giving the axle torque and the horsepower delivered, including rolling friction of the tires, and readings in connection with the traction-wheel tire speed, can be obtained.

**Motor plows and ground-breaking machinery.** HOLLDACK (*Jahrb. Deut. Landw. Gesell.*, 27 (1912), No. 1, pp. 203-219, pls. 15, figs. 11).—A discussion is

given of motor plows and ground breakers in general, describing some special improved types, including combinations of motor and high-speed rotating ground breakers and presenting a graphical discussion of the losses in the drive wheel by slipping and sinking and special improved types of drive-wheel rim to prevent this.

**The application of motor plows, E. FREUND** (*Wiener Landw. Ztg.*, 62 (1912), No. 45, pp. 543, 544).—A description and discussion are given of three systems of motor plowing, namely, the rope and windlass system, the drag system, and the combination tractor and ground-breaker system, giving tables showing the horsepower, revolutions per minute, weight, fuel, required, cost of operation, and initial cost of the different makes of each system.

[**A powerful ditching machine**] (*La. Planter*, 48 (1912), No. 19, p. 336, fig. 1).—A powerful ditching engine is described which pulls a bull ditcher back and forth between the main canals of an irrigation system, thus making a system of connecting ditches between the main canals. It is claimed that the ditcher can be operated at a speed of 3,000 ft. per hour.

**A new machine for picking cotton** (*Texas Farm Co-operator*, 35 (1912), No. 36, p. 1, fig. 1).—A description is given of a new cotton picker, the mechanism of which consists of a 16-in. cylinder 12 in. long, on which are mounted 20 spindle-shaft frames each carrying 7 spindles, making 140 picking fingers in all. As the cylinder revolves, the spindles are caused to revolve at high speed as they stand in a vertical position and the cotton wraps around them. When they come to a horizontal position they are thrown out of gear and the cotton is stripped off and passed to a basket in the rear. It is claimed that this picker will do the work of from 10 to 12 men, requiring only a team and driver.

**A new fruit-tree sprayer, C. PLATZ** (*Mitt. Prüf. Stat. Landw. Masch. u. Geräte Halle*, 1912, No. 164, p. 24, figs. 21).—This pamphlet reports the results of investigations on a fruit-tree sprayer, consisting of a pressure cylinder, containing compressed air and the liquid to be applied, an air pump to supply the air pressure, a manometer to measure and gage the air pressure, a gage to regulate the supply of the liquid, and a hose with an adjustable spray nozzle, the whole being fitted with the necessary valves. The theory of the operation of this apparatus is explained and the results of pressure measurements, investigations of power required in pumping the pressure, time duration of discharge, discharge efficiency, and nozzle efficiency are given.

The conclusions are that although the apparatus in practice may not be as efficient under all conditions as the investigations show, yet it combines simplicity, ease of operation, and relatively high efficiency.

**Milking machines and mechanical milking, C. HUYGE** (*Ann. Gembloux*, 22 (1912), No. 5, pp. 251-308, figs. 24).—This article describes several different makes of milking machines operated by suction, compression, and suction and compression combined, and discusses the important principles of their operation and the advantages and disadvantages of mechanical milking in general, pointing out the bad effects that some machines have on the cow, and the advantages of time saving, sanitation, and flexibility of mechanical milking apparatus.

**Preliminary examinations of new dairy apparatus, B. MARTINY** (*Arb. Duct. Landw. Gesell.*, 1912, No. 219, pp. 101, figs. 41).—This work describes and gives the results of preliminary investigations of new dairy machinery and apparatus, among which are cream separators, churns, refrigerating machinery, heating apparatus, and apparatus for testing milk and cream.

**Dairy barn at University of Missouri, C. H. ECKLES** (*Wallaces' Farmer*, 37 (1912), No. 16, pp. 751, 752, figs. 2).—The ground plan and general descrip-

tion of the dairy barn at the University of Missouri are given. The construction is intended to be practical and to include at the same time all the necessary features for the best sanitary conditions.

**The farm stable.** C. W. SLEIGH (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 24 (1912), pp. 49-52, figs. 10).—The essential details of the construction of suitable farm stables are briefly given, emphasizing drainage, ventilation, light, and the comfort of the horses, and presenting original ideas as to roof, wall, floor, and stall construction.

**Experiments with improved cow stalls.** A. GÜNTHART (*Wiener Landw. Ztg.*, 62 (1912), No. 45, pp. 549, 541, figs. 5).—The details of a cow stall are given in which a double, adjustable hanging chain is used instead of stanchions.

**Cement silo construction.** (*Agr. Ed. [Kans. Agr. Col.]*, 4 (1912), No. 6, pp. 79, figs. 29).—This bulletin gives a detailed outline of the design and construction of the monolithic silo, by G. S. Hine, and of the metal-lath silo, by G. C. Wheeler.

**Farm poultry houses.** J. B. DAVIDSON and W. A. LIPPINCOTT (*Iowa Sta. Bul.* 132, pp. 227-251, figs. 15).—This bulletin sets forth the essentials of a good poultry house, and emphasizes the necessity of a well-drained location and of dryness, ventilation, sunlight, and simplicity in construction to facilitate cleaning and disinfection. Plans and specifications and details of construction, with bills of material and estimates of cost, of an A-shaped portable colony house, the Iowa Station colony house, and a farm poultry house are also given.

**Making a poultry house.** M. R. CONOVER (*New York*, 1912, pp. 54, pls. 8, figs. 4).—This work deals with the design and construction of poultry houses and contains chapters with specific suggestions for houses, floors, foundations, roofs, walls, windows and ventilation, doors, nests and roosts, and the run, and a final chapter on general upkeep.

**Wire fencing.** (*Canad. Thresherman and Farmer*, 17 (1912), No. 7, pp. 57, 58).—It is stated that the rusting of modern steel wire is due principally to galvanic action rather than to the thinness of the galvanizing coat, this action being brought about by the difference in chemical composition of different parts of wire manufactured from iron made by the Bessemer and open-hearth processes. When iron containing considerable manganese is used, the different iron particles of different chemical composition are caused to act as different metals, assume different potentials, and when wet cause the flow of electric currents, thus setting up galvanic action and resulting in a decomposition of the wire.

The puddled iron process is presented as a solution to the rust problem since in this process the slag and impurities are more evenly distributed throughout the metal, thus preventing galvanic action. Wire made from puddled iron is more expensive than the others, but is considered an economical investment since it lasts from 4 to 5 times as long.

See also the work of Cushman (*E. S. R.*, 21, p. 207).

**Labor-savers in the laundry.** L. R. BALDERSTON (*Country Gent.*, 77 (1912), No. 20, p. 13, *dgms.* 5).—Laundry machinery and equipment is discussed, particularly with reference to farm laundry problems.

## RURAL ECONOMICS.

What is the most important problem before our rural people? (*Business America*, 12 (1912), No. 5, pp. 49-57).—Answers to the above question are presented, as follows: Education, by A. C. True; The Problem of Marketing, by F. A. Waugh; Cooperation, by C. S. Barrett; Where Are Rural People to Spend Their Money and Energy? by T. N. Carver; The District School, by E. T. Fair-

child; The Labor Income, by W. H. Wilson; and Enlarging the Agricultural Unit, by E. Davenport.

**Cost accounting on farms.** G. F. WARREN (*Amer. Agr.*, 90 (1912), No. 13, pp. 263, 264, 265).—An address delivered before the New York State Agricultural Society in which the author compares incomes of farmers and city laborers, and discusses the cost of men and teams on the farm, equipment value, interest on investment, and various factors usually omitted in keeping farm accounts. He states that reports of receipts and expenditures as secured from 2,409 farms in 14 townships in New York indicated that but one-third of the farmers made more than hired man's wages in addition to 5 per cent interest on their capital. A similar study in 6 other States indicated that less than one-third of the farmers make farm wages.

**Colonization and immigration.** J. S. DUFF (*Rpt. Min. Agr. Ontario, 1911*, pp. 49-53, figs. 2).—Data are presented showing that 2,356 immigrants were sent to Ontario farms by the Bureau of Colonization and Immigration during the year ended October 31, 1911. The number of farm laborers sent by the Salvation Army is reported as 1,431.

The sum of \$20,000 has been set apart for advancing part of the passage money of those who gave promise of being desirable laborers or servants. Repayments were made to an average extent of \$20 each, and the plan is regarded as progressing satisfactorily.

[Cooperative agricultural distribution and production], G. S. BARNES (*Rpt. Indus. and Agr. Coop. Soc. United Kingdom, 1899-1910*, pp. XXXIII-XXXIX, 61-69).—Tables are given showing the number, membership, sales, etc., of the cooperative societies in the United Kingdom, 1895-1909.

It is noted that the number of productive societies increased from 46 in 1895 to 317 in 1909 with an increase in membership from 3,110 to 45,622. They had at the end of 1909 a sale, loan, and reserve capital of £431,348. The total sales for the year amounted to £2,005,314, upon which a profit of £23,663 was made.

A large majority of these organizations are dairying societies scattered over a considerable area and confine their operations to collecting the milk of their members and separating the cream, which they send to a central creamery. "This system of central creameries with a number of auxiliary societies is found to result in economy in manufacturing expenses, and in the reduction in the competition which ensues when a large number of small societies are each endeavoring to secure customers for their output in the same markets."

The number of distributive societies increased from 11 in 1895 to 334 in 1909; the membership from 2,418 to 39,339; the sale, loan, and reserve capital from £7,745 to £162,758; sales from £56,092 to £1,343,390; and profits from £1,032 to £12,613.

**Life insurance as a means of promoting the redemption of mortgages and the acquisition of land** (*Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intcl.*, 3 (1912) No. 8, pp. 129-146).—This article discusses at length some recent applications of the principles of life insurance in connection with agriculture, giving special attention to an experiment made by certain Prussian *Landschaften* to attain, by means of life insurance, the discharging of mortgages on rural property and the investment of the money of the farmers participating in projects to the advantage of agriculture and of their local communities.

A lengthy bibliography is included.

**Agricultural insurance in Denmark** (*Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intcl.*, 3 (1912), No. 4, pp. 75-102).—This article presents a detailed examination of agricultural insurance against fire, storms, hail, live stock, etc., as they have developed in the Danish peninsula and islands, show-

ing the working details, progress, etc., of each class of insurance for a period of years.

**Cooperative insurance societies, 1899-1909**, G. S. BARNES (*Rpt. Indus. and Agr. Coop. Soc. United Kingdom, 1899-1910, p. 76*).—There are in England and Wales a number of small cattle and pig insurance societies, the membership of which consists of small holders who raise by periodical assessments a common fund for mutual insurance against loss by the death of their live stock. A table is here given showing the membership, receipts, expenditures, etc., of these societies for each year from 1899 to 1909 inclusive. In 1909 there were 57 active societies with an aggregate membership of 3,954, the receipts during the year amounting to £2,256, and the expenditure to £2,295, of which £387 was for working expenses.

**Royal Agricultural Benevolent Institution**, W. GILBEY (*Live Stock Jour. [London], 76 (1912), No. 2003, p. 197*).—This article calls attention to the work of the Royal Agricultural Benevolent Institution of England, which seeks to provide for bona fide farmers, their wives, widows, and unmarried orphan daughters when in distress. At present 1,252 pensioners are maintained at an annual cost of £25,092. Since the institution was founded in 1869 over 4,600 persons have been granted annuities at a total cost of £710,084.

**The land mortgage association of Germany**, H. C. PRICE (*Wallaces' Farmer, 37 (1912), No. 39, pp. 1361, 1362*).—This article presents a study of the land mortgage associations of Germany and describes their working operations in detail.

The plan usually followed is for the landowners desiring to borrow money to form an association, and instead of each member negotiating his loan individually, they pool their interests and issue bonds against the association. The individual members give their mortgages to the association for their loans and these secure the bonds. As the members are also liable for the bonds to the full extent of their property, this gives the bonds a ready market value and makes them a favorite investment. The farmer receives a bond in return for the mortgage he gives to the association, and this he can sell personally or through the bank established in connection with the association. He usually pays 4 per cent interest on the loan, in addition to 0.25 per cent for operating expenses of the association and 0.75 per cent toward paying off the loan, so that he pays both the interest and the loan in 40 or 45 years. His rate of interest can not be increased during this time nor can his mortgage be foreclosed.

**Uruguayan rural credit bank**, N. A. GREVSTAD (*Daily Cons. and Trade Rpts. [U. S.], 15 (1912), No. 167, p. 300*).—This report notes that by an act of January 19, 1912, a section of rural credit with an initial capital of \$500,000 was established in the central bank of Uruguay. The formation of cooperative rural credit banks to be owned by local farmers was also authorized, these to borrow from the central bank in proportion to their relative size and importance, and in turn to loan small sums to their individual members. The central bank will exercise a kind of supervisory control in regulating the general terms of the loans and mortgages, inspecting the accounting at stated periods, and aiding generally to insure the safety and efficiency of the capital invested.

**The Rhodesia land bank**, W. OLIVE (*Rhodesia Agr. Jour., 9 (1912), No. 6, pp. 837-841*).—This article describes the conditions and circumstances leading to the establishment of the Rhodesia land bank, together with regulations under which its work is carried on.

This institution was established to stimulate the agricultural development of Rhodesia by the advancement of money to small farmers on the security of landed property, other than town property, or on approved security. Among the principal conditions under which advances are made, are the following: Ad-

vances are made on first mortgage or for the purpose of purchasing land or to enable existing liabilities to be paid off, for the purchase of live stock, agricultural implements, etc., or for effecting improvements on land, including farm buildings, fencing, irrigation works, and afforestation. Loans may not exceed £2,000 to any one person, interest is charged at the rate of 6 per cent per annum, payable semi-annually, and loans are repaid in installments apportioned over a period not exceeding 10 years, beginning with the third year, but may be paid in a shorter period.

**Social centers in the Southwest**, C. W. HOLEMAN and C. D. MURPHY (*Dallas, Tex., 1912, new ed., pp. 34, figs. 11*).—This booklet discusses and illustrates the origin and growth of the social center movement in the Southwest, the needs and value of the work, and how social centers may be organized and definitely what can be done to sustain them.

**Agricultural statistics, 1911** [Province of British Columbia], A. E. CRADDOCK (*Dept. Agr. Brit. Columbia Bul. 45, 1912, pp. 38, figs. 5*).—Statistics are given relating to the acreage of various crops, the number of live stock, and crop production in each of the specified districts of the Province of British Columbia for 1911. The agricultural resources are also shown as a whole, together with the estimated value of products during the year.

**Agricultural statistics 1910-11**, E. LAHITTE (*Agr. Statis. Argentina [English Ed.], 1910-11, pp. 11+107, pl. 1*).—This is a report of the Division of Agricultural Statistics and Rural Economy in Argentina for 1910-11, including data on the area of cultivated land: area, yields, and value of principal crops, and returns per hectare from wheat, flax, corn, and oats from 1891 to 1910; imports and value of farm machinery and implements; rural properties, loans, and mortgages; distribution and consumption of live stock; and exports and value of farm products.

It is noted that Argentina furnished to the United Kingdom 20,613 tons of beef and 55,740 tons of mutton in 1900 and 252,057 tons of beef and 75,507 tons of mutton in 1910. The total value of the agricultural, live stock, forest, hunting, and fishing exports amounted to 153,415,751 pesos (\$148,046,200) in 1900 and 369,081,620 pesos in 1910.

**Agricultural statistics of Ireland**, with detailed report for the year 1911, T. BUTLER (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1911, pp. XXXV+147*).—This is a detailed report showing the division of land from 1841 to 1911; acreage under crops and yields by counties and Provinces; number and description of holdings; number and ages of live stock; and other agricultural data. The total area of the country is reported at 20,345,328 statute acres, of which 11.5 per cent was planted to corn, green crops, flax, and fruit in 1911, 12.4 per cent was under hay, and 48.4 per cent is classed as rotation and permanent pasture; the remainder consisting of bogs, barren mountains, water, roads, building lands, wastes, etc.

**Agricultural statistics, Ireland, 1912**, T. BUTLER (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1912, pp. 31*).—Data similar to the above are given for 1912.

**Foreign crops, April, 1912**, H. C. GRAHAM (*U. S. Dept. Agr., Bur. Statis. Circ. 36, pp. 15*).—This circular notes that British India, with a population of over 300,000,000 people and a total area of 1,138,075,482 acres, has 223,000,000 acres under cultivation. About 20 per cent is irrigated, over  $\frac{1}{3}$  from government canals. Of the areas under various crops, rice with 78,731,137 acres in 1910 leads in relative importance, millet follows with 38,105,334 acres, then wheat with 22,769,918 and cotton with 13,172,188 acres. The yield of rice ranges from 700 to 1,200 lbs. per acre, wheat from 510 to 1,250 lbs. and cotton from 30 to 308 lbs. of lint per acre.

A number of tables are given showing crop areas for a number of years; the area irrigated from canals, tanks, wells, etc., by Provinces and States; the area, production, and exports of the principal crops, by countries; and other data.

**Foreign crops, May-June, 1912.** C. M. DAUCHERTY (*U. S. Dept. Agr., Bur. Statis. Circ. 37, pp. 19*).—This circular gives notes and statistics respecting crop conditions in various countries, together with tables showing exports of domestic wheat, wheat flour, barley, oats, flaxseed, apples, and cheese from Canada, 1903-1912; the area and production of wheat and flaxseed in British India, by Provinces, 1912 and 1911; imports of wheat and wheat flour into the United Kingdom, 1907-1911; preliminary estimate of areas under grain, etc., in France, May 1, 1912, 1911, and 1910, and final estimate of areas sown in 1911 and 1910; imports of wheat into France and Germany by countries of origin, calendar years 1907-1911; production of olives and olive oil in Spain, 1911-12, by regions; area sown to specified crops in Hungary, 1912 and 1911; area and production of specified crops in Roumania, 1911-1909; and area, production, and exports of wheat in Australia, 1900-1912; and other data.

### AGRICULTURAL EDUCATION.

**The present trend of agricultural education.** L. A. CLINTON (*Penn. Dept. Agr. Bul. 213, 1911, pp. 178-184*).—This is a discussion of the work of the agricultural colleges and experiment stations and of the efforts being made at present to reach the individual farmer.

**A redirection of agricultural education.** C. L. BEACH (*Ann. Rpt. Conn. Bd. Agr. 43 (1910), pp. 19-25*).—The author briefly discusses the function and scope of the experiment station, the agricultural college, and agricultural extension work, and notes a "redirection of agricultural education at the present time, or rather the shifting of the emphasis, from the activities of the college and the station to that of agricultural extension."

**Statistics of state universities and other institutions of higher education partially supported by the State for the year ended June 30, 1911.** (*U. S. Bur. Ed. Bul., 1911, No. 19, pp. 23*).—This bulletin includes statistics of agricultural colleges and items of interest concerning progress in them.

**Arkansas state agricultural schools.** C. H. LANE (*U. S. Dept. Agr., Office Expt. Stas. Bul. 250, pp. 20, pls. 5*).—A report on a system of special agricultural schools established by a State without reference to existing political divisions and furnishing concrete information as to the origin, equipment, organization, and work of the 4 schools comprising it.

**Equipment and profitableness of the farms of agricultural education institutions.** (*Land u. Forstw. Unterrichts. Ztg., 25 (1911), No. 3-4, pp. 287-312*).—This is a summary of information compiled from replies to 141 circular letters addressed to the agricultural education institutions in Austria by the minister of agriculture concerning the ownership, object, principal features of work, profits, value of land and equipment, etc., of their farms.

**Educational and illustrative material for instruction in rural economics in vocational schools and association lectures.** GEIBEL (*Arb. Deut. Landw. Gesell. 1910, No. 167, pp. 255-266*).—This is a description of the illustrative material for instruction in rural economics shown at the Eisenach exhibition of agricultural illustrative material made by agricultural teachers and pupils.

**A working erosion model for schools.** D. C. ELLIS (*U. S. Dept. Agr., Office Expt. Stas. Circ. 117, pp. 11, figs. 4*).—A description is given of a model designed to illustrate graphically the erosion of hillsides and the destruction of farms in the lower valleys following the complete removal of forests from the hills.

It can easily be constructed in a school building for use by classes in nature study, agriculture, and physical geography.

**Farm management field studies and demonstration work in Ohio**, L. H. GODDARD (*Ohio Sta. Circ. 127*, pp. 172-182, figs. 2).—An outline is given of a plan which has been adopted by the department of cooperation of the Ohio Station and the Office of Farm Management of this Department, for reorganizing the extension work which has been conducted by the station. This is followed by an account of the purpose and character of the work to be undertaken, previous experience in extension work at the Ohio Station, an agricultural survey of the State, the use of district supervisors and county agents, township supervision, farm management extension work, rural economics, and rural sociology.

Proceedings of the twenty-fifth annual convention of the Association of American Agricultural Colleges and Experiment Stations, edited by J. L. HILLS (*Proc. Assoc. Amer. Agr. Colls. and Expt. Stas.*, 25 (1911), pp. 229).—An account of this convention, held at Columbus, Ohio, November 15-17, 1911, has been given (E. S. R., 26, p. 8).

Proceedings of the sixteenth annual meeting of the American Association of Farmers' Institute Workers, edited by W. H. BEAL and J. HAMILTON (*U. S. Dept. Agr., Office Expt. Stas. Bul. 251*, pp. 77).—An account of this convention, held at Columbus, Ohio, November 13 and 14, 1911, has been previously given (E. S. R., 26, p. 199).

List of agricultural and horticultural officials, institutions, and associations (*Verslag, en Meded. Dir. Landb. Dept. Landb., Nijv en Handel, 1912, No 2*, pp. 120).—This list contains the organization and personnel of the Department of Agriculture, Industry, and Commerce, including the agricultural education service, agricultural education and research institutions, agricultural and horticultural winter schools, itinerant agricultural and horticultural instructors, and agricultural and horticultural associations in the Netherlands.

### MISCELLANEOUS.

**Thirty-fifth Annual Report of Connecticut State Station, 1911** (*Connecticut State Sta. Rpt. 1911, pt. 6*, pp. XVIII).—This contains the organization list, a report of the board of control, in which are embodied minutes adopted in memory of the late Dr. William H. Brewer, a financial statement for the fiscal year ended September 30, 1911, and a list of corrections to the report.

**Annual Report of the New Jersey Stations, 1910** (*New Jersey Stas. Rpt. 1910*, pp. XVIII+124, pls. 69, figs. 5).—This contains the organization list of the stations, a financial statement for the State Station for the fiscal year ended October 31, 1910, and for the College Station for the fiscal year ended June 30, 1910, a brief report by the director, and departmental reports, the experimental features of which are abstracted elsewhere in this issue. A report on the inspection of fertilizers has been previously noted (E. S. R., 24, p. 528), as have also been a report on the inspection of feeding stuffs (E. S. R., 23, p. 475) and an account of peach investigations at Vineland and High Bridge (E. S. R., 23, p. 734).

**Monthly Bulletin of the Department Library, July and August, 1912** (*U. S. Dept. Agr., Library Mo. Bul.*, 3 (1912), Nos. 7, pp. 209-229; 8, pp. 233-264).—These numbers contain data for July and August, 1912, respectively, as to the accessions to the Library of this Department and the additions to the list of periodicals currently received.

## NOTES.

---

**Alabama College and Station.**—Percy F. Williams, professor of horticulture and forestry and state horticulturist, died December 4, at the age of 29 years. Professor Williams was graduated from the Massachusetts College in 1905, and after a period of commercial landscape gardening became assistant horticulturist in the station in 1908, and head of the department in the college and station two years later. He introduced the study of landscape engineering into the college, and in the station has been the author of numerous horticultural bulletins, notably on the Satsuma orange and the pecan, in which he was particularly interested.

**California University and Station.**—Additional appointments include President John W. Gilmore, of the Hawaii College, as professor of agronomy, and A. V. Stuberauch, of the pomological investigations of this Department, as professor of pomology. J. E. Coit, associate professor of pomology and superintendent of the citrus substation at Riverside, has been made professor of citriculture, with headquarters at Berkeley.

**Connecticut College.**—Roy E. Jones has been appointed instructor in poultry husbandry.

**Georgia College.**—John T. Newton and J. A. Thrash have been reappointed to the board of trustees. J. E. Turlington has resigned as instructor in agronomy in the extension department.

**Iowa College.**—A. M. Ten Eyck, formerly superintendent of the Fort Hays substation in Kansas, has been appointed to the farm crops section of the extension department.

**Maine University.**—George A. Yeaton, orchardist, and Albert Verrill, assistant chemist, have resigned, the former to take up county demonstration work and the latter to enter commercial work. Elmer R. Tobey has been transferred to the position of assistant chemist.

**New Jersey College.**—A course in home economics is being offered for the first time as one of the short winter courses, beginning November 18 and ending February 28. It includes such special subjects as chemistry of foods, home management, horticulture, dairying, home sanitation, and invalid and infant cookery.

**Ohio University and Station.**—Over 100 students have been registered in the college of agriculture, which is now considerably the largest in the university. An apprentice course in animal husbandry, in which alternate years are spent in the university and on some live-stock farm selected by the department, is a new feature.

Ross M. Sherwood, George R. Green, E. P. Arzberger, H. R. Watts, J. B. Demaree, J. T. Rogers, and L. E. Melchers, assistants in forestry, animal husbandry, and botany, have severed their connection with the station. The first-named has accepted the position of instructor in poultry husbandry at the Iowa College.

**Oregon College.**—The stock judging pavilion was burned to the ground October 25, causing an estimated loss of \$7,500. The structure is to be replaced immediately from state funds available for the reconstruction of state buildings destroyed by fire.

**Pennsylvania College and Station.**—Dr. William A. Buckhout, professor of botany and botanist, died December 3, at the age of 66 years. Dr. Buckhout was a graduate of the college in the class of 1868 and received the master's

degree in 1871 and that of doctor of science in 1904. His long career was spent entirely at the college, beginning in 1871 with his appointment as professor of natural history. Ten years later his title was changed to that of professor of botany and horticulture, and in 1907 to that of professor of botany and botanist. For many years he was botanist to the State Board of Agriculture, and in 1888 a member of the State Forestry Commission, doing much to promote interest in forestry. Among his investigations may be mentioned those on the effect of smoke and gas on vegetation.

**Clemson College and Station.**—Beginning with the next session the college is to give an intensive one-year agricultural course to students over 18 years of age who are familiar with the practical side of farming. Scholarships of \$100 each and free tuition are to be given to one student from each county and to 7 from the State at large.

Recent appointments include F. T. Wilson as assistant professor of agronomy and assistant agronomist, M. P. Somes as assistant professor of entomology and zoology and assistant entomologist, O. M. Clark as assistant professor of horticulture, C. F. Niven as assistant in horticulture, T. R. Haden as assistant in animal husbandry, and F. H. Jeter as assistant to the director.

**Wisconsin University and Station.**—Sixteen farmers' meetings have been held this fall on county asylum and other public farms throughout the State, to demonstrate the crops grown on these farms by their superintendents in cooperation with, and under the supervision of, the college of agriculture. At 7 of these plowing contests for prizes were held, and at 4 domestic science lectures and demonstrations were given in the kitchens.

The soils department has held 6 demonstration meetings showing the effects of different treatment of the soils in several parts of the State. Most of these were held on the sandy soils where much benefit has been gained by turning under alfalfa and other legumes for green manure.

The dairy cattle breeders of the State have formed 59 community breeders' associations for the purpose of improving the breeding of their cattle and cooperation in buying of feed and marketing of stock, etc.

Frank B. Moody, a graduate of the forestry school of the University of Michigan, has been appointed assistant professor of forestry, and is to organize a school for forest rangers and give courses on woodlot management in the university.

**Miscellaneous.**—According to a note in *Rural New Yorker*, the General Education Board announced October 25 that it was about to begin free agricultural demonstrations for farmers in the North. Allotments of \$1,500 were made for St. Lawrence County, N. Y., under the direction of the State School of Agriculture at Canton, and of \$8,000 for four counties in Maine, under the direction of the University of Maine.

Lai Kuei Liang, a 1908 graduate of the Massachusetts Agricultural College, has been appointed vice minister of agriculture and forestry in the Chinese Republic, and has begun the issue of the *Chinese Agricultural Journal*.

E. L. Hsieh, a 1909 graduate of the same college, is chief of the bureau of interpretation of the same department, and is engaged in translating into Chinese the agricultural literature of other countries. H. Jen, also a 1909 graduate, is director of the agricultural experiment station at Mukden, Manchuria.

C. S. Orwin, editor of the *Journal of the Royal Agricultural Society*, has been appointed director of the Institute for Research in Agricultural Economics, recently established at Oxford University in cooperation with the Development Commission.

Prof. Etienne Foëx has been nominated assistant director of the Plant Pathological Station at Paris, France.

# EXPERIMENT STATION RECORD.

VOL. XXVII.

ABSTRACT NUMBER.

No. 9.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

On the composition of the ash of the sap, leaves, and young stems of the wild grapevine (*Vitis cordifolia*), O. M. SNEED and J. H. KASTLE (*Jour. Amer. Chem. Soc.*, 34 (1912), No. 10, pp. 1415-1424).—After reviewing the results obtained by other investigators, the authors report analyses of a sample of sap obtained April 14 from the cut ends of a wild grapevine, and for purpose of comparison analyses of the leaves and young stems taken June 16, as follows:

*Composition of the ash of the sap, leaves, and young stems of the wild grapevine (V. cordifolia).*

Determination.	Sap (by weight).		Leaf.		Stem.	
	I. Ash of sap.	II. Fresh sap.	III. Ash of leaf.	IV. Green leaf.	V. Ash of stem.	VI. Green stem.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Water at 100°.....		99.5340		75.4709		79.2500
Crude ash.....		.1130		2.3300		1.0200
Organic matter.....		.2782		22.8500		20.0437
Silica.....	0.405	.0005	5.890	.1372	0.400	.0041
Ferric and aluminum oxids.....	.540	.0006	.920	.0214	.030	.0003
Calcium oxid.....	19.490	.0220	30.900	.7209	10.920	.1114
Magnesium oxid.....	3.900	.0044	5.740	.1337	3.390	.0346
Soda.....	1.500	.0017	1.530	.0356	1.680	.0171
Potash.....	41.380	.0468	14.710	.3427	38.070	.3883
Phosphorus pentoxid.....	5.090	.0058	9.700	.2260	12.520	.1277
Sulphur trioxid.....	4.590	.0052	2.720	.0634	2.240	.0228
Nitrogen as nitrates.....		.0075		.0045		.0056
Chlorin, sap only.....		.0008				

The sap had a faintly acid taste, was slightly acid to litmus, and 2.8 cc. of decinormal sodium hydroxid solution was required to neutralize 100 cc. of the sap against phenolphthalein. Its specific gravity was 1.0035.

Composition of sweet apricot kernels, L. ROSENTHALER and W. SCHAEFFER (*Pharm. Zentralhalle*, 52 (1911), No. 19, pp. 507, 508; *abs. in Chem. Zentbl.*, 1911, II, No. 1, p. 35; *Analyst*, 36 (1911), No. 426, pp. 450, 451).—The composition of the kernels, obtained from the south of France, was as follows: Water 4.33, total soluble matter 27.87, protein 31.4, oil 53.4, reducing sugars 8.08, reducing sugars after hydrolysis 11.64, crude fiber 4.76, and ash 2.6 per cent.

"The oil expressed from the kernels had the following physical and chemical properties: Specific gravity at 15° C., 0.9182;  $[N]_D^{25}$  64.7; solidifying point, 14.5°; iodine value, 95.03; saponification value, 187.76; Reichert-Meissl value, 0.96; insoluble fatty acids, 73.48 per cent. The oil was optically inactive. The fatty acids gave the following values: Solidifying point, 5.1°;  $[N]_D^{25}$  53.7; iodine value, 98.41; mean molecular weight, 290.55. The oil yielded negative results with Halphen's, Baudouin's, Soltsien's, and Becchi's tests, but gave a blue-violet coloration with Bellier's test, the coloration developing gradually and fading in a few minutes. The elaidin test yielded a viscous mass."

The kernels, which were edible, had a pleasant almond-like taste. They were quite different from those obtained from Japan.

**Chemical-physiological examination of the tubercles on the radicles of the bean.** G. SANI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 19 (1910), II. No. 4, pp. 207-211; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 30 (1911), No. 4-6, p. 75).—Among the nitrogenous substances of the bean nodules the author detected asparagin, glycocholl, and phenylalanin. The total amount of nonprotein nitrogen was 0.003 per cent. A proteolytic enzyme was also isolated.

**Biochemical and toxicological studies on *Penicillium stoloniferum*,** C. L. ALSEBERG and O. F. BLACK (*Orig. Commun. S. Internat. Cong. Appl. Chem. [Washington and New York]*, 19 (1912), Sect. VIII d, pp. 15-23).—"From cultures of *P. stoloniferum* Thom. obtained from a sample of spoiled maize from Italy, a new phenolic acid of the formula  $C_{17}H_{20}O_6$  was isolated in crystalline form. It resembles the lichen acids, is not toxic, and is one of the substances causing the ferric chlorid reaction of Gosio in deteriorated maize."

**Progress made in the field of chlorophyll chemistry,** E. W. MAYER (*Chem. Ztg.*, 35 (1911), Nos. 145, pp. 1341-1343; 146, pp. 1354-1356; 147, pp. 1364, 1365).—This is a review of the work done in the field of chlorophyll chemistry.

**Enzymes,** P. BERGELL (*Abs. in Chem. Ztg.*, 36 (1912), No. 8, pp. 68, 69).—This is a review of the present status of enzyme chemistry.

**Investigations in regard to the chemical composition and formation of enzymes, III.** H. EULER and S. KULLBERG (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 71 (1911), No. 1, pp. 14-30; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II. Ref., 4 (1911), No. 8, p. 427).—In contrast to zymase, invertase appears to be independent of the protoplasm. As the fermentation of cane sugar goes on as quickly as that of glucose and fructose it seems that the inversion process proceeds much quicker than the fermentation process. The concentration of the cane sugar solution has some influence upon both processes, irrespective of the type of yeast used in the tests. The fermentation of cane sugar goes on in the interior of the cell.

**Studies on enzyme action.—II. The hydrolytic action of some amino acids and polypeptids and certain esters,** K. G. FALK and J. M. NELSON (*Jour. Amer. Chem. Soc.*, 34 (1912), No. 6, pp. 828-845).—In this work, which is a continuation of the investigations previously noted (E. S. R., 27, p. 712), the quantity of acid produced when methyl acetate, ethyl butyrate, and olive oil was dissolved or suspended in aqueous solutions containing glycine, alanine, phenylalanine, leucine, glycylglycine, leucylglycine, glycyllucine, diglycylglycine, aspartic acid, and glutamic acid at 38° C. was determined.

"Glycine and alanine show the greatest amount of hydrolysis with ethyl butyrate and least with methyl acetate. Phenylalanine, on the other hand, shows a markedly greater action with methyl acetate, less with ethyl butyrate, and least with olive oil. Leucine gave practically no action with any of the three esters. Glycylglycine gave the same slight action with methyl acetate and ethyl butyrate but none with olive oil. With leucylglycine, glycyllucine, and digly-

glycine, maximum, though small, actions were obtained with ethyl butyrate, very slight but distinct with olive oil, while with glycyll-leucin and diglycyl-glycine and methyl acetate negative values were obtained. Not enough measurements were made with the former to make this last result certain."

The authors point out that despite the results obtained above there is no evidence at hand that the hydrolysis of fats, etc., by lipase is due to amino acids or polypeptides.

**A proteolytic enzyme in the must of overripe grapes.** E. PANTANELLI (*Centbl. Bakt. [etc.], 2. Abt., 31 (1911), No. 23-25, pp. 545-559; abs. in Zentbl. Biochem. u. Biophys., 12 (1912), No. 19-20, p. 824*).—The must of overripe white and red grapes was found to contain an enzyme which cleaves protein to products which are not precipitated by copper hydroxid.

**The use of elastin for detecting proteolytic enzymes.** E. ABDERHALDEN and K. KIESLWETTER (*Hoppe-Seyler's Ztschr. Physiol. Chem., 74 (1911), No. 4-5, pp. 411-426; abs. in Chem. Abs., 6 (1912), No. 8, p. 1015*).—Enzymes can be demonstrated in feces, various organs, and press-juices from them with the aid of elastin. A study made of the digestion of elastin and of native and coagulated egg albumin by gastric juice and pepsin-hydrochloric acid with the aid of the optical method indicated that the results obtained with gastric juice and pepsin-hydrochloric acid are not at all comparable.

**The ferment nature of peroxidase.** GRIMMER (*Milchw. Zentbl., 41 (1912), No. 6, pp. 165-168*).—Milk peroxidase apparently has nothing to do with the alkalinity or the inorganic constituents of milk. Peroxidase is of an organic nature and closely associated with lactalbumin.

**Activation of sucrase by various acids.** G. BERTRAND and M. and MME. M. ROSENBLATT (*Compt. Rend. Acad. Sci. [Paris], 153 (1911), No. 26, pp. 1515-1518; abs. in Zentbl. Biochem. u. Biophys., 13 (1912), No. 4, p. 167*).—The action of a large number of acids and acid salts was studied as regards their power of accelerating the activity of sucrase (invertase), and with particular reference to the optimum concentration of these acids.

**The chemical constitution of the proteins.** R. H. A. PLIMMER (*New York, Bombay, and Calcutta, 1912, 2. ed., pt. 1 pp. XII+188, figs. 6*).—In this second edition (E. S. R., 21, p. 210) a more detailed analysis of the proteins is given.

**The precipitation of proteins by zinc sulphate.** F. LIPPICH (*Hoppe-Seyler's Ztschr. Physiol. Chem., 74 (1911), No. 4-5, pp. 360-391; abs. in Chem. Abs., 6 (1912), No. 8, p. 1010*).—"When protein is precipitated by increasing concentrations of zinc sulphate, there are 2 maxima of precipitation, the first beginning at 0.08 to 0.1 normal, the second at 1.8 to 2 normal; between lies a minimum at which the liquid remains for a time clear. Equal volumes (5 to 10 cc.) of diluted horse serum were treated with graduated amounts (0.1 to 1 cc.) of a saturated solution of zinc sulphate, and made up to a round volume (50 to 200 cc.). The conditions corresponded to rapid equilibrium at the lower maximum. The precipitates contained, independently of the concentration of protein and the original concentration of zinc sulphate, always the same amount of zinc. The capacity of the protein to combine with zinc apparently increases with the dilution; that the zinc precipitated per unit volume remains the same seems to indicate a combination in constant proportions. The precipitations produced at the second maximum contain about twice as much zinc. The results are difficult to reconcile with the absorption hypothesis. They suggest rather a balanced reaction according to the scheme:  $ZnSO_4 + 2Na \text{ protein} \rightleftharpoons Na_2SO_4 + Zn(\text{protein})_2$ . Most of the facts can be explained by the further assumption that, as salt concentration and other conditions vary, there arise such types of compound as  $ZnSO_4, \text{ protein}; Zn, \text{ protein}, -ZnSO_4$ ; and  $Zn, \text{ protein}.$ "

**Dilatometric investigation in regard to the precipitation of proteins,** G. GALEOTTI (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 78 (1912), No. 6, pp. 421-434, fig. 1).—No variation in volume takes place during the coagulation of proteins by either enzymes or heat. During the precipitation of egg albumin with the so-called precipitating reagents an increase in volume takes place, which is dependent upon and differs with the precipitating reagent employed. It is greatest with ammonium sulphate, less with the salts of heavy metals, and least with potassium ferrocyanid, phosphotungstic acid, and tannic acid.

**The progressive hydrolysis of fats,** A. GRÜN and O. CORELLI (*Ztschr. Angew. Chem.*, 25 (1912), No. 14, pp. 665-670; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 9, p. 442).—When pure tripalmitin was treated for several hours with sulphuric acid of 66° B. at 70° C. in the proportion of 10 molecules of acid to 1 of glycerid, a fatty acidity equal to 56.5 per cent was obtained. This shows that a diglycerid is produced from a triglycerid without the production of mono-glycerid. Similar results were obtained when tristearin was treated in the same way. Attempts to isolate intermediary products failed.

**The hydrolysis and constitution of lecithin,** F. MALENGREAU and G. PRIGENT (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 77 (1912), No. 2, pp. 107-120).—The authors found that it was possible with the aid of heat to hydrolyze lecithin completely with either a decinormal sulphuric acid solution or a decinormal hydrochloric acid solution. The process takes about 5 or 6 hours, but has the advantage of not leaving an excess of acid present at the end of the process. Cholin does not influence the reaction.

**Note on hydrolysis of vegetable oils by emulsion of Ricinus communis,** D. SOMMERVILLE (*Bio-Chem. Jour.*, 6 (1912), No. 2, pp. 253, 254).—No difference was noted in the amount of hydrolysis with castor oil or cotton-seed oil when treated with an emulsion of the castor bean, therefore it is concluded that the enzyme of the castor bean does not act specifically toward its own oil. The author was not able to note any acceleration of hydrolysis by acetic acid and manganese sulphate. The lipase of the castor bean was not refractory to heat when protected by oil. Heating the emulsion to 60° C. destroyed the enzyme. The bean from which the emulsion was obtained was stable when heated at 100° for 24 hours.

"Cotton oil and castor oil, when carefully neutralized and freed from proteins fail to undergo hydrolysis. If to this oil an enzymic emulsion, in which hydrolysis of fat has not yet commenced, be added, nothing results. If hydrolysis is established in the emulsion, the hydrolysis proceeds in the added oil, irrespective of whether this oil be neutral or contain within wide limits (25 per cent) free fatty acids."

**The hydrolysis of saccharose by various acids in the presence of invertase,** C. BERTRAND, M. and MME. M. ROSENBLATT (*Bul. Soc. Chim. France*, 4, ser., 11 (1912), No. 4, pp. 176-186; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 6, p. 294; *Ztschr. Angew. Chem.*, 25 (1912), No. 21, p. 1083).—It is concluded that with invertase and perhaps with other soluble ferments we must assume that in the presence of specific colloidal substances the activity of the acid does not depend entirely upon the hydrogen ion which results from the electrolytic dissociation, but is also greatly dependent upon the nature of the radicles or anions to which the hydrogen in the acid molecule is bound.

**An unrecognized source of error in the Kjeldahl-Gunning method for the determination of nitrogen,** P. A. W. SELF (*Pharm. Jour. [London]*, 4, ser., 34 (1912), No. 2527, pp. 384, 385).—The author sought to ascertain the cause for the low results which were often obtained with the Kjeldahl-Gunning method when comparatively large amounts of material were employed. The results of

the investigation show that where 25 cc. of sulphuric acid is used in the method 15 gm. of sulphuric acid should remain behind.

The amount of material to be taken for each determination is  $3\frac{1}{2}$  gm. for cereals or a material containing much carbohydrate, while the limit for fat-containing material should vary from 3 gm. for a sample containing from 5 to 10 per cent of fat and 1.5 gm. for material containing from 80 to 90 per cent. The amount of acid should be proportionately increased when small amounts of nitrogen are present.

**Determination of total potassium in minerals,** C. J. SCHOLLENBERGER (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 6, pp. 436, 437, fig. 1).—When potassium alone is to be determined the J. L. Smith method is long and tedious and the modifications thereof leave much to be desired. The following method has been used with success in the laboratory of the Ohio Station:

“Proceed as in the regular Smith method for total alkalis until the filtrate from washing out the alkalis from the fusion is obtained. To this add a moderate excess of hydrochloric acid and evaporate to dryness on a steam bath, remote from ammonia fumes. Take up with about 2 cc. of concentrated hydrochloric acid and 25 cc. of hot water, and filter through [an Ames] suction filter into a 150 cc. beaker, washing the large beaker and filter well. Add the proper amount of hydrochloroplatinic acid solution, and evaporate on steam bath until of a semisolid consistency. The large amount of calcium chlorid present crystallizes out on cooling, but is readily soluble in acidulated alcohol. The crystalline precipitate of the potassium chloroplatinate is washed with acidulated alcohol, Gladding wash, and 80 per cent alcohol, on a filter designed especially for this work. After drying to remove alcohol, the precipitate is dissolved in hot water, the solution being received in a tared platinum dish, and after evaporation, dried and weighed.”

The Ames filter, which possesses several advantages over the Gooch crucible filter for collecting and washing the potassium platonic chlorid, is described and illustrated.

**Carbon dioxid:** Its volumetric determination, L. T. BOWSER (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 3, pp. 203–205, figs. 2).—This is a modification of the Mims method, and consists essentially of releasing the carbon dioxid from the substance under examination by means of hydrochloric acid, absorbing it in a strong alkaline solution, and measuring the absorbed gas by titration with a standard acid solution with the aid of a suitable apparatus. The apparatus is depicted, and consists of an Erlenmeyer flask holding a small separatory funnel, a short Liebig condenser having an inner tube of very small bore, and an absorbing tower. The absorbing tower consists of a glass tube containing some glass beads for the purpose of dividing the carbon dioxid, and 10 cc. of potassium hydroxid solution (50 gm. of potassium hydroxid in 100 cc. of solution) for absorbing the carbon dioxid.

**On the determination of carbon dioxid in soils,** L. T. BOWSER (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 4, pp. 265, 266).—The method described above is considered especially adaptable to soils containing small amounts of carbon dioxid, giving more consistent results than the method generally employed.

**Determination of sulphuric acid in the soil,** P. DE SORNAY (*Internat. Sugar Jour.*, 13 (1911), No. 153, pp. 497–500; *abs. in Zentbl. Biochem. u. Biophys.*, 13 (1912), No. 4, p. 132).—The usual method for determining sulphuric acid in soils is deemed inexact, especially if much aluminum and iron are present. The following method is recommended for this purpose:

Ten gm. of the soil is mixed with 1 gm. of potassium nitrate and 5 cc. of water, dried on the sand bath, calcined, and treated with 25 cc. of hydrochloric

acid. The heating is continued until the mass is absolutely dry and the silicic acid is rendered insoluble. Fifty-five cc. of water and 20 cc. of hydrochloric acid are then added and the whole is heated for from 30 to 45 minutes on a sand bath, being careful not to go to the point of dryness. After filtering, the residue on the filter is washed with from 100 to 125 cc. of water. To the filtrate and washings barium chlorid is added, heated, concentrated slightly, and the remainder of the procedure conducted in the usual manner.

**Report of committee of the fertilizer division of the American Chemical Society, F. B. CARPENTER ET AL.** (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 3, pp. 223-225).—This is a report of the committee on fertilizer legislation (potash, phosphate rock, and nitrogen), presented at the forty-fifth meeting of the American Chemical Society, held at Washington, D. C. in December, 1911.

**Methods of organic analysis, H. C. SHERMAN** (*New York, 1912, 2. ed., rev. and enl., pp. XVI+407, figs. 18*).—This publication (E. S. R., 17, p. 732) has been rewritten and enlarged to include a chapter on solid and liquid fuels, and sections on industrial alcohol, drying oils, crude petroleum, new international methods of glycerin analysis, and quantitative methods for assaying enzymes. The discussions on aldehydes, sugars, proteins, and food preservatives have been somewhat extended.

**Allen's commercial organic analysis, edited by W. A. DAVIS and S. S. SADLER** (*Philadelphia, 1912, 4. ed., rev., vol. 6, pp. IX+726, pls. 2, figs. 6*).—This volume has been entirely rewritten. Among its contents are methods of analysis of amins and ammonium bases, anilin and its allies, naphthylamins, pyridin, quinolin and acridin bases, vegetable alkaloids, volatile bases of vegetable origin, nicotin and tobacco, aconite alkaloids, atropin and its allies, cocaine, opium, strychnos alkaloids, cinchona alkaloids, berberine, caffen, tea and coffee, and cocoa and chocolate. The properties of the above substances are also discussed.

**A modified Wiley extraction apparatus, W. D. RICHARDSON and E. F. SCHERUBEL** (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 3, pp. 220, 221).—The Wiley apparatus has been modified into three forms so that it may be used for the extraction of tankage, cotton-seed meats and meals, meat and sausages, soap, etc.

**New reactions for salicylic acid, E. BARRAL** (*Bul. Soc. Chim. France, 4 ser., 11 (1912), No. 8, pp. 417-420*).—A description of 4 new reactions.

**In regard to the macroscopic and microscopic detection of carotin, M. TSWETT** (*Ber. Deut. Bot. Gesell.*, 29 (1911), No. 9, pp. 630-636; *abs. in Zentbl. Biochem. u. Biophys.*, 12 (1912), No. 19-20, p. 778).—Molisch's potassium and Tswett's resorcin methods are not specific reactions for detecting carotin microscopically, and they indicate only lipochromes, that is, carotin groups, which in the end means very little. Doubt also exists as to whether the red crystals obtained with the Frank and Tschirch acid method are in reality composed entirely of carotin. In all events, it will be necessary to investigate the work of those whose results were obtained with these methods, in regard to the distribution of carotin in the vegetable kingdom. It is believed that macroscopic methods will have to be used in future investigations.

**The detection of adulterations by colloidal chemical methods, E. MARRIAGE** (*Ztschr. Chem. u. Indus. Kolloide*, 11 (1912), No. 1, pp. 1-5, figs. 8).—As many of the fruit juices and other materials used in the manufacture of jellies and marmalades are first passed through filter presses, the materials entering into their composition can be detected only with difficulty by the usual microscopic methods. With the thought in mind that colloidal chemical methods might be effective for this purpose experiments were conducted with the following mixtures: (1) Agar (1 per cent), gel 46 gm., cane sugar 10 gm.;

(2) agar (1 per cent), gel 50 gm., cane sugar 20 gm.; (3) apple jelly; (4) apple jelly 8 parts, agar gel (agar 2½, sugar 50, water 47½ per cent) 2 parts; (5) apple jelly 6 parts, agar gel with sugar 4 parts; (6) gooseberry jelly; (7) apples 53 parts, and gooseberries 12 parts; (8) starch; (9) gelatine; (10) orange marmalade; and (11) currant jelly. The reagents used were potassium iodid and a cold saturated solution of lead nitrate. About 5 per cent of potassium iodid was added to the heated jelly, followed on cooling by the lead nitrate solution.

The lead iodid precipitate produced was found to vary in structure with the material tested. Its structural characteristics can best be studied with the microscope, although the differences can be noted macroscopically. Sugar when present seemed to influence considerably the size of the lead iodid granules produced. Emphasis is placed on the fact that much work will have to be done in this direction and that the experimental data should be accompanied by photographs for the purpose of determining the utility of the method for food inspection work.

**A method for the determination of starch in food products,** T. M. PRICE (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 203, pp. 6*).—This is a combination of the desirable features present in the Perrier and the Bigelow-Mayrhofer methods, and the elimination of the objectionable features contained in them. The method is as follows:

“In a 200 cc. beaker treat 10 gm. of finely divided meat with 75 cc. of an 5 per cent solution of potassium hydrate in 95 per cent alcohol, and heat on the steam bath until all the meat is dissolved. This will require from 30 to 45 minutes. Add an equal volume of 95 per cent alcohol, cool, and allow to stand at least 1 hour. Filter by suction through a thin layer of asbestos in a Gooch crucible. Wash twice with warm 4 per cent potassium hydrate in 50 per cent alcohol and then twice with warm 50 per cent alcohol. Discard the wash water. Endeavor to retain as much of the precipitate in the beaker as possible until the last washing. Place the crucible with contents in the original beaker, add 40 cc. of water and then 25 cc. of concentrated sulphuric acid. Stir during the addition of the acid and see that the acid comes in contact with all the precipitate. Allow to stand about 5 minutes, add 40 cc. of water, and heat just to boiling, stirring constantly. Transfer the solution to a 500 cc. graduated flask, add 2 cc. of a 20 per cent aqueous solution of phosphotungstic acid, allow to cool to room temperature, and make up to mark with distilled water. Filter through a starch-free filter paper, and determine the dextrose present in a 50 cc. portion of the filtrate with Fehling's solution after neutralizing the acid, using Low's method . . . for the determination of the copper in cuprous oxid precipitate. The amount of dextrose multiplied by 0.9 gives the equivalent in starch.

“The accuracy of the above-described method was demonstrated through its application to a number of samples of sausages to which known amounts of pure cornstarch had been added.”

**Determination of nucleic acid in the flesh of mammalia,** A. SCALA (*Ann. Ig. Sper., n. ser., 20 (1910), No. 4, pp. 509-520; abs. in Zentbl. Biochem. u. Biophys., 13 (1912), No. 1-2, p. 9*).—The method rests upon the principle that when nucleic acids are treated with barium chlorid a precipitant of barium nucleinate is obtained.

**Composition of dry gluten and its relation to the protein content of flour,** G. A. OLSON (*Jour. Indus. and Engin. Chem., 4 (1912), No. 3, pp. 206-209*).—Believing that perhaps the reason for high-protein flours containing relatively more gluten than flours which are low in protein was due to a larger content of impurities, the author made tests with gluten from flours representing

wheats of the Bluestem, Red Russian, Turkey Red, Fife, Dale, Little Club, Galgalos varieties, and of hybrids cultivated at the Washington Station.

Summarizing results it would seem that "gluten as it is ordinarily prepared has a variable nitrogen, ash, starch, and moisture content. The peculiar copper reduction resulting from adding the filtered extract from hydrolyzed gluten by acid is undoubtedly due to some other substance than starch or sugar. An average of about 75 per cent of the total nitrogen of flour enters into the crude gluten. Glutens obtained from low-protein flours are not necessarily any richer in nitrogen, more free from ash, etc., than glutens derived from medium- or high-protein flours. The reason why low-protein flours yield much lower percentages of gluten than medium- or high-protein flours may be attributed to the scattering of such glutens, resulting in mechanical loss. Blending such flours with strong gluten flours results in yields comparable to those obtained for medium- and high-protein flours."

**Contribution to the examination of flour.** E. KOHN (*Chem. Ztg.*, 36 (1912), No. 14, pp. 121-123).—For detecting foreign substances in flour, i. e., by-products, the author utilized the following method:

One-half gm. of flour is well shaken with 10 cc. of ether in a test tube and poured in a comparatively flat, large, porcelain dish. Bran, plant hairs, and wheat particles are removed from the surface of the liquid upon which they float or the ether is allowed to evaporate and the particles removed from the residue by means of a preparation needle. The particles are then washed with a little water to remove the adhering starch grains and examined in chloral hydrate. An optional qualitative method is also given.

To detect wheat, bean, or barley flour in rye flour, the author allows diastase to act on flours in an acid medium and then determines the density or the sugar content of the hydrolyzed mixture. The figures obtained are greatest for rye flour, least for bean flour, and greater for wheat flour than barley flour.

**The Watkins test for determining the cause of sliminess in bread.** H. KÜHL (*Chem. Ztg.*, 35 (1911), No. 143, pp. 1321, 1322).—There are two methods which may be used for detecting the presence of the organisms which produce sliminess in bread, namely, the baking test in which 450 gm. flour and 240 cc. of water at from 40 to 42° C. are employed, and the Watkins test,<sup>a</sup> which is based on the fact that the bacteria producing the viscosness contain spores which resist temperatures varying between 80 and 100°, whereas spore-free bacteria are thermolabile. The latter method is of particular value where only small quantities of flour are available for the test, and it can also be employed for obtaining pure cultures of slime-producing bacteria. Some experiments with the method are reported.

**The chemical differentiation of fermentation vinegar and vinegar essence, with particular reference to their formic acid content.** H. FINCKE (*Deut. Essigindus.*, 15 (1911), No. 19, pp. 145-148).—This is a discussion of work previously noted (E. S. R., 25, p. 311; 26, p. 208).

**Standards for malt vinegar.** A. C. CHAPMAN (*Pharm. Jour. [London]*, 4, ser., 34 (1912), No. 2527, p. 394).—The author maintains that malt vinegar complying with the requirements set down by the U. S. Department of Agriculture as regards methods of manufacture may give analytical results well outside of the standards laid down.

"Thus, it is shown that in cases where fermentation has been very completely effected the malt vinegar may have a levorotatory instead of a dextrorotatory action on polarized light, owing to the disappearance of the dextrorotatory carbohydrate matters, and to the presence of levorotatory proteins.

<sup>a</sup> Jour. Soc. Chem. Indus., 25 (1906), No. 8, pp. 350-357.

It is also pointed out that in the case of malt vinegar made with hard water the proportion of soluble phosphate acid may fall much below the limit laid down in the Department's regulations."

**Determining the shell or hull content of cocoa by A. Goske's method,** F. SCHMIDT and J. GÖRNING (*Ztschr. Öffentl. Chem.*, 48 (1912), No. 11, pp. 201-214).—This is a study of the Goske method (E. S. R., 23, p. 12), which indicates that the method is unsatisfactory, especially where the cacao products have been previously prepared and ground finely. The shell content of prepared cocoa, containing from 25 to 50 per cent of shells, can not be determined with any degree of accuracy.

**In regard to the detection of adulterations in paprika,** A. VON SIGMOND and M. VUK (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 23 (1912), No. 8, pp. 387, 388).—Previously noted from another source (E. S. R., 27, p. 715).

**Artificial coloration of foods and condiments,** E. SPAETH (*Pharm. Zentralblatt*, 52 (1911), Nos. 10, pp. 243-251; 11, pp. 282-291; 12, pp. 310-316; 13, pp. 336-343; 14, pp. 368-374; 15, pp. 409-413; 17, pp. 459-467; 31, pp. 813-818; 32, pp. 839-843; 33, pp. 866-868; 34, pp. 893-897; 35, pp. 919-924; 36, pp. 948-953; 37, pp. 967-971; 38, pp. 998-1004; 40, pp. 1062-1067).—This is a continuation of the work previously noted (E. S. R., 25, p. 712), and deals with the artificial coloring of conserved vegetables, crab butter (crab extract and crab powder), anchovies, caviar, egg conserves, tea, coffee, and chocolate.

**Some observations on the modified LaWall method for the determination of sodium benzoate in catsups,** W. D. MCABEE (*Ann. Rpt. Ind. Bd. Health*, 29 (1910), pp. 323, 324).—These studies were made with catsups which were first tested as to their freedom from benzoic acid, and known amounts of the acid then added. The method as modified by La Wall and Bradshaw (E. S. R., 20, p. 211) was found to be very accurate. Fifty gm. of catsup was used instead of 200.

**Methods for determining the fat in milk,** O. RAMMSTEDT (*Ztschr. Angew. Chem.*, 25 (1912), No. 16, pp. 754-758).—The neu-sal method, when conducted with the acid butyrometric apparatus, was found to yield values which are comparable with those obtained by the Gerber acid butyrometric test and the Röse-Gottlieb method. The sal method on the other hand yields higher results. For heated milk the neu-sal method is thought to yield correct results, although this is contrary to the finding of other authors. The author advises, however, that the coloring matter used in the reagent should be eliminated. No acid reaction toward litmus was noted in the reagent.

Other comparative tests carried out indicate that with whole milk the Gerber acid butyrometric, the Gerber neu-sal, and the sand method (with 2 extractions of 6 hours each) yield comparable results. The Funke method yielded results which were slightly higher. The Adams, Röse-Gottlieb and usual sand methods, while comparable among themselves, gave lower results than the afore-mentioned. With top milk the following figures were obtained: "Neu-sal" and Funke 6.6 per cent, Röse-Gottlieb 6.34 per cent, Adams 6.33 per cent, acid butyrometric 6.4 per cent, sand (single extraction) 6.28 per cent, and sand (double extraction) 6.49 per cent.

**Detection of watered milk by Cornalba's method,** F. BORDAS and F. TOUPLAIN (*Ann. Falsif.*, 5 (1912), No. 42, pp. 171-173).—The figures for total soluble solids in the serum from 100 cc. of milk were somewhat lower than those reported by other authors, varying from 5.169 to 5.94, with an average of 5.49. These differences are probably due to the use of different reagents for preparing the serum and this must be taken into account when adopting the method as a standard.

**A portable outfit for the determination of visible dirt in milk,** F. O. TONEY (*Amer. Jour. Pub. Health*, 2 (1912), No. 4, pp. 280, 281, figs. 2).—This apparatus consists of a Gooch crucible filter attached to a Chapman filter pump which has a rubber collar for fitting over an ordinary faucet. The filtering material consists of a very thin disk of absorbent cotton.

**Comparative investigations of the bacteriological and biochemical methods for judging milk,** O. SCHROETER (*Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 6-12, pp. 181-192).—Of the 122 samples of milk utilized in this work, 89 samples consisted of ordinary market milk, 28 samples of a special milk in the original bottles, 3 samples of milk drawn in the barn of the agricultural institute of the University of Leipsic, one skim milk, and one milk purposely mixed with the milk obtained from cows suffering with mastitis. The following observations were made: (1) The total germ content on meat extract, whey-, Heyden-, and Ragit-agar, after 3 days at 38° C.; (2) the number of lactic-acid bacteria (according to Beijerinck) upon calcium carbonate-whey-agar plates; (3) the number of coli bacteria (according to Harrison and Vanderleek) in esculin bouillon; (4) the amount and character of the sediment obtained in the leucocyte test (Trommsdorff); (5) the microscopic picture of the centrifuge residue; (6) the results obtained with the catalase test with 15 cc. of milk plus 5 cc. of 1 per cent hydrogen peroxid at 20° C., with a special form of apparatus, which is described; (7) the reductase test (O. Jensen); (8) the milk fermentation test at 38°; (9) the degree of acidity (Soxhlet-Henkel); and (10) the alcohol and boiling test.

**The catalase and reductase tests for the examination of milk,** G. GEUDENS (*Handl. Vlaamsch Natuur en Geneesk. Cong.*, 15 (1911), pp. 108-111).—A description of the procedures and apparatus used for the catalase and reductase tests. The interpretation of the results is also considered.

**The Schardinger reaction of cow's milk,** P. H. RÖMER (*Biochem. Ztschr.*, 50 (1912), No. 1-2, pp. 5-14).—This is a reply to Rullmann (*E. S. R.*, 25, p. 785), supported by experimental data to show that the initial milk almost always gives a negative Schardinger test. Commercial milk samples taken at Marburg, Germany, were often found to yield negative results. The reaction will not, therefore, indicate whether a given sample of milk has been heated or not.

**The effect of cooling milk upon the outcome of the Schardinger reaction,** R. BURRI and H. SCHMID (*Biochem. Ztschr.*, 36 (1911), No. 5-6, pp. 376-388, figs. 4).—The formaldehyde-methylene blue reduction reaction is somewhat dependent upon the temperature to which the milk was previously subjected. Cooling reduces the time of reduction, which probably means an increase in the enzym content. The solidification of the milk fat globules in this connection is also considered.

**The behavior of sterile and boiled milk with rennet and acid,** A. KREIDL and E. LENK (*Biochem. Ztschr.*, 36 (1911), No. 5-6, pp. 357-362).—Boiled, as well as sterile milk, can be coagulated with rennet. Sterile vessels for holding the milk, or sterile rennet, are not necessary, and in fact, sterile milk with an acidity not over 22 cc. of tenth-normal acid when treated with sterile rennet in a sterile vessel will not coagulate, though touching the milk so kept with an unsterile finger, or the addition of a few drops of ordinary milk, will bring about coagulation. The lactic-acid bacillus multiplies best in a slightly acidified milk (from 0.2 to 0.6 cc. of tenth-normal acid to 10 cc. of milk). The addition of an acid to a sterile milk contained in a sterile vessel, to the extent of 2 cc. tenth-normal hydrochloric acid to 10 cc. of milk, produces no precipitation, even after acidification at blood heat.

**The reaction of rennet on milk,** M. NIERENSTEIN and JESSIE STUBBS (*Jour. Agr. Sci.*, 4 (1912), No. 4, pp. 371-375).—The conclusions drawn in this work

were as follows: (1) The acidity of milk is not due entirely to the formation of lactic acid, but partly to some product produced from caseinogen. (2) Pure lactic acid cannot be used as a starter in Cheddar cheese making, though it stimulates the production of acid from caseinogen. (3) The retardation of the time of coagulation with rennet is not entirely dependent on the calcium salts.

Investigations in regard to the hemolytic action of cow's colostrum, W. KÖBELE (*Centbl. Bakt. [etc.], 1. Abl., Orig., 61 (1912), No. 7, pp. 561-589; abs. in Centbl. Bakt. [etc.], 1. Abl., Ref., 52 (1912), No. 21, p. 653*).—The colostrum of some cows contains amboceptor and complement, the former being extinct 2 days post-partum. Both of these are present in the initial and end milk in about the same quantity. They originate from the blood serum which gains access to the milk during the colostrum period.

In regard to milk hemolysis, B. SCHMIDT (*Arch. Kinderheilk., 56 (1911), No. 4-6, pp. 342-358; abs. in Berlin. Tierärztl. Wechschr., 28 (1912), No. 27, p. 501*).—The hemolytic method advocated by Bauer and Sassenhagen (*E. S. R., 23, pp. 114, 513*) for detecting colostrum and mastitic milk was found satisfactory. Instead of using guinea-pig blood rabbit blood can be employed. When bovine serum is used it must be previously titrated.

Viscosimetric studies on human milk, K. BASCH (*Wiener Klin. Wechschr., 24 (1911), No. 46, pp. 1592-1595; abs. in Chem. Abs., 6 (1912), No. 5, p. 645*).—The viscosity was diminished as the period of lactation went on, until it reached a constant value.

A small contribution from dairy laboratory practice, M. SIEGFELD (*Molk. Ztg. [Hildesheim], 26 (1912), Nos. 34, pp. 617, 618; 35, pp. 631-633*).—This is a discussion in regard to Storch's reaction, the determination of fat according to the Gottlieb method, the determination of fat in cream, the composition of various proprietary preservatives for milk and milk products and other preparations, determinations of iron in curd which indicate that the Schaeffer test (*E. S. R., 22, p. 212*) is unreliable and the potassium sulphocyanid test is more satisfactory, the detection of iron in dairy salt, and other data. In some of the tests mentioned improvements and substitutions are suggested.

Detection of iron in cheese curd, H. SCHERER (*Molk. Ztg. [Hildesheim], 26 (1912), No. 40, pp. 738, 739*).—The author maintains that aside from the fact that the results when obtained on the bases of Schaeffer's color table only refer to 20 gm. of curd instead of 100 gm. of curd, the method is practical and exact and can be used without any difficulty by the practical dairyman. Siegfeld's contentions (see above) are therefore not considered to be entirely borne out.

Detection of iron in cheese curd, M. SIEGFELD (*Molk. Ztg. [Hildesheim], 26 (1912), No. 45, p. 838*).—In reply to Scherer (see above), the author points out that iron is not present in a soluble form nor is it evenly distributed in the cheese curd. The reason that Scherer obtained a stronger reaction with ammonium sulphid than with potassium sulphocyanid was probably because of the uneven distribution of the iron in the cheese samples which he examined.

Determination of moisture and fat in cheese, H. LÜHRIG and E. NOCKMANN (*Molk. Ztg. [Hildesheim], 26 (1912), No. 37, pp. 669-671*).—Some comparative tests were made with two methods, (a) and (b), for determining the moisture content of cheese. In method (a) from 3 to 5 gm. of the cheese mass, mixed with ignited sand or pumice stone in a platinum dish, is dried in a vacuum desiccator for a few days and then for 8 hours in a steam bath at from 97 to 99° C. Method (b) utilizes the same amount of cheese, evenly distributed in a platinum dish and heated first on a water bath and then finished in a glycerin water bath at from 102 to 105° for from 4 to 6 hours.

Both methods yield practically the same result, but (a) is recommended because it is more conveniently conducted. The Bondznski-Ratzloff method is recommended for determining the fat in cheese.

**Method for determining salt and fat,** R. H. SHAW (*Cream. Jour.*, 23 (1912), No. 10, pp. 12, 13, 16, fig. 1).—Previously noted (E. S. R., 27, p. 614).

**The adulteration of butter,** A. ELOIRE (*Hyg. Viande et Lait*, 5 (1911), No. 12, pp. 681-697; 6 (1912), No. 1, pp. 12-33).—This is a review of existing methods for detecting abnormal butter and adulteration in butter. The results of examining different kinds of butter are also included.

**Methods of detecting adulterations in butter,** L. ROBIN (*Ann. Falsif.*, 5 (1912), No. 42, pp. 180-187).—This is a simplification of the methods previously noted (E. S. R., 18, p. 709). It describes the preparation of the reagents and the procedure for determining fatty acids soluble in alcohol, the fatty acids soluble in water, and the fatty acids insoluble in water but soluble in alcohol, with the interpretation of the results obtained.

**Determination of fat in feed stuffs and seeds,** M. MONHAUPT (*Chem. Ztg.*, 35 (1911), No. 141, p. 1305).—A formula is given for calculating the fat content of certain substances when determining the fat by the shaking-out method. An aliquot of the ethyl ether or petroleum ether extracts is taken for the determinations. The formula can also be employed in all cases where a soluble constituent of known specific gravity is shaken out with a definite amount of appropriate solvent from the substance under examination.

**A method for differentiating sterilized from unsterilized bone meal,** E. POLENSKE (*Arb. K. Gsndhtsam.*, 38 (1912), No. 4, pp. 559-561).—As ground bones are often used for feeding stock, including poultry, and may have originated from diseased animals, the author recommends the following method for determining whether or not the bone has been sterilized.

Ten gm. of the meal is mixed with 30 cc. of cold water and allowed to stand for 24 hours, shaking occasionally during this time. The mixture is then filtered and the filtrate poured back upon the filter until a clear fluid is obtained. To 10 cc. of the filtrate is added 2 drops of concentrated acetic acid, the mixture brought to the boiling point, and the tube with its contents placed in a water bath held at 95° C. for ½ hour. If a flocculent deposit is produced the material was not sterilized previously.

**In regard to the behavior of invert sugar in an alkaline solution and in the presence of hydrogen peroxid,** A. JOLLES (*Biochem. Ztschr.*, 36 (1911), No. 5-6, pp. 389-393).—This is a continuation of the work previously noted (E. S. R., 26, p. 307).

Comparison between the double polarization method of determining sucrose and the direct polarization after destruction of the reducing sugars, H. PELLET (*Internat. Sugar Jour.*, 14 (1912), No. 159, pp. 161, 162; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 7, p. 351).—"A number of comparative determinations with the Pellet-Lemeland and other methods of determining sucrose have been carried out, the following results being obtained: Direct polarizations, defecating with basic lead acetate, 33.7; direct polarization, using hypochlorite and normal lead acetate for clarification, 28.9; direct acid polarization, using hydrochloric acid and urea (Andrflk), 30.9; sucrose by double polarization, using the neutral direct polarization, and verified constants, 33.9; sucrose by double polarization, employing the acid (Andrflk) direct polarization, and verified constants, 33.6; direct polarization, after destruction of the reducing sugars, by the Pellet-Lemeland procedure, 33.8; sucrose by double polarization, using the solution in which the reducing sugars had been destroyed by the Pellet-Lemeland process, 33.5; sucrose by determining the reducing sugars before and after inversion, and operating directly on the

sample, 38.3. Six other samples were also examined by the double polarization method and the results compared with those found by direct polarization after the destruction of the reducing sugars by the Pellet-Lemeland method, the following being the figures obtained: By the double polarization method, using for the direct reading the solution clarified with hypochlorite and defecated with normal lead acetate: (1) 45.3; (2) 39.4; (3) 39.7; (4) 35.9; (5) 40.2; and (6) 37.5; and by direct polarizations, after destruction of the reducing sugars: (1) 46.3; (2) 39.4; (3) 37.5; (4) 35.5; (5) 39.0; and (6) 38.4."

**Gravimetric determination of saccharose by oxidation with chromic acid.** A. WECHSLER (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 40 (1912), No. 5, pp. 683-703, figs. 1).—Saccharose when present alone is oxidized in a special form of apparatus, which the author calls an "oxydimeter," with a mixture consisting of 500 cc. of commercial sulphuric acid, 300 cc. of water, and 100 gm. of chromic acid. Fifty cc. of this mixture is added to an amount of saccharin substance which will contain on an average from 0.15 to 0.25 gm. of carbon to be oxidized. Inorganic substances when present have no influence upon the oxidizing process. The results obtained by the method for refined sugar and beet extracts agreed well with the polarimetric findings. Basic lead nitrate was used as the precipitating and clearing agent for the beet pulp. A new method for determining the ratio of saccharose to nonsugar during the process of manufacture, on the basis of the oxidizing and polarimetric test, is also included.

**The inversion of saccharose by bees' honey.** O. ACHERT (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 4, pp. 136-139).—A honey-saccharose mixture in which the honey was never heated to over 55° C. showed an inversion of the saccharose to the extent of reducing it from 22.05 to 2.21 per cent in a period of 4 months. Heating to 100° destroyed the inverting enzyme, as found by Moreau (*E. S. R.*, 26, p. 312). Acids like formic play no part in the inversion process, as neutralized samples were found to be inverted much more quickly and to a greater extent than those containing free acid.

**Incrusting coloring matter of sugar cane.** L. C. LANGGUTH-STEUERWALD (*Arch. Suikerindus. Nederland. Indië*, 19 (1911), No. 47, pp. 1543-1557; *Meded. Proefstat. Java-Suikerindus.*, 1911, pp. 365-379, pl. 1; *abs. in Deut. Zuckerindus.*, 37 (1912), No. 1, pp. 5, 6; *Chem. Ztg.*, 34 (1912), No. 12, *Repert.*, p. 55).—In the cane, and apparently also in the cane juice, a new coloring substance, which is termed saccharetin, was noted. The purified substance corresponded to the formula  $(C_8H_7O_2)_n$ , has the characteristics of a phlobaphene, is light yellow in color, optically inactive, slightly acid, and is soluble only in alcohol, glacial acetic acid, and alkalis.

**The Andrlík method of polarization as applied to cane products.** H. PELLET (*Internat. Sugar Jour.*, 14 (1912), No. 157, pp. 28-30).—If a sufficient amount of lead salts is added to pure sugar solutions about to be tested according to the Andrlík procedure, constant polarizations can be maintained for some time. Instead of the dextrorotatory power being decreased, as is the case with the usual procedure, it is slightly increased, this being due to the volume of lead precipitated.

The author points out that he has collected the results of a large number of experiments with different products of cane and beet-sugar manufacture, and that these show that when the above mentioned factors are considered, good results can be obtained with the method. In some tests between the Andrlík hydrochloric acid and urea method (*E. S. R.*, 26, p. 207) and the Pellet sulphurous acid method for beet molasses the results obtained were practically the same.

In regard to determining the acidity of cane juice, P. A. YODER (*Jour. Induc. and Engin. Chem.*, 3 (1911), No. 9, pp. 640-646, figs. 2; *abs. in Ztschr. Angew. Chem.*, 25 (1912), No. 21, pp. 1082, 1083).—Most of the literature in regard to the determination of acids in wine fermentation products, fruit juice, etc., does not take into account the aconitic acid which is usually present, and which constitutes in Louisiana cane juice most of the acidity present. The utility of the well-known existing methods for isolating and determining the various acids present and the behavior of these acids and their salts toward solvents were studied. It was found that aconitic acid, succinic acid, and lactic acid can be easily removed quantitatively from the juice by extraction with ether, but tartaric, malic, and citric acids can not be isolated satisfactorily by this method.

In testing the solubility and the precipitability of the calcium salts of these acids the salt of aconitic acid was found to have the same property which calcium citrate possesses, i. e. precipitation by heat from its aqueous solution. The solubility of calcium malate in 50 per cent alcohol gives a basis for a method for separating it from other acids except lactic acids. The barium salts behave like the calcium salts in regard to solubility. The separation of aconitic acid from succinic acid in the shape of the acid ammonium salt was not satisfactory. Denigès' method was satisfactory for detecting citric acid but has the objectionable feature that it is also positive for aconitic acid.

A practical illustration for determining the several acids from cane juice is given.

Some recent work on molasses analysis, W. E. CROSS (*La. Planter*, 48 (1912), No. 22, pp. 382, 383).—A critical review of the literature in this regard.

The determination of nitrogen in betain, H. STOLTZENBERGER (*Ztschr. Ver. Deut. Zuckerindus.*, 1910, No. 675. II, pp. 440-445).—This is a contribution to the question of determining nitrogen in molasses and vinasse.

Complete oxidation of the betain can only be brought about by heating the sample with concentrated sulphuric acid for several hours. By the addition of copper sulphate, mercuric oxid, and phosphorus pentoxid to the acid mixture, the oxidation process can be accelerated considerably. To determine the nitrogen in substances containing betain the following procedure is recommended by the author:

About 3 gm. of molasses or 2 gm. of vinasse is placed in a 500 cc. Kjeldahl flask and 25 cc. of a sulphuric acid-phosphorus pentoxid mixture (100 gm. of phosphorus pentoxid in a liter of acid) and 1 gm. of powdered potassium sulphate and 1 gm. of mercuric oxid added. The mixture is then heated until decolorized, and 1 hour in addition. After cooling and diluting with 120 cc. of water, 2.2 gm. of powdered sodium thiosulphate and  $\frac{1}{2}$  teaspoonful of pipe-clay are added; the pieces of clay must have the size of a pinhead or of small shot. After setting up a receiver which contains 50 cc. of decinormal hydrochloric or sulphuric acid for collecting the distillate, 90 cc. of a 22 per cent sodium hydrate solution is added to the mixture, the flask quickly connected with the condenser and distilled until bumping begins. The remainder of the process is the usual one.

Extraction of oil from the olive, E. MINGIOLI (*Petite Rev. Agr. et Hort.*, 18 (1912), No. 421, pp. 133, 134).—A description of the Acapulco method and its advantages and disadvantages.

A comparative study of methods for the determination of hard and total soft resins in the hop, H. V. TARTAR and C. E. BRADLEY (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 3, pp. 209-212).—This is a comparative study of some of the present methods, including Briant and Meacham's, Siller's,

Lintner's volumetric method for soft resins (original and modified), and the authors' methods for determining the resin constituents of hops. The authors' methods, which they think will overcome some of the objections present in the other methods, are as follows:

"Ten gm. of hops is placed in a Soxhlet extractor and extracted with ether for 8 to 10 hours. The ethereal extract thus obtained is filtered and the filtrate made to 200 cc. volume.

"Total resins.—One hundred cc. of the ether solution (equivalent to 5 gm. of hops) is placed in a 250 cc. Erlenmeyer flask and nearly all of the ether removed by distillation on a water bath at about 40° C. The last portion of the ether is completely removed by drying in a vacuum desiccator at room temperature. The residue remaining is then taken up with alcohol to free the wax, filtered, and the filtrate made to 100 cc. volume. A 20 cc. aliquot (equivalent to 1 gm. of hops) is transferred to a tared beaker and the alcohol removed by evaporation in a vacuum oven at 50° to constant weight. The residue thus obtained is the total resins in 1 gm. of hops.

"Total soft resins.—The remaining 100 cc. of the original ether extract is transferred to a 200 cc. Erlenmeyer flask and the ether nearly removed by distillation at low temperature, the last portion being removed by evaporation in a vacuum desiccator at room temperature. The residue is taken up with about 100 cc. of petroleic ether (boiling point 40 to 45°). The residue is worked up in the solvent with a glass rod and then let stand a short time to effect the complete solution of the soft resins in the solvent. The hard resin is then removed by filtration. The petroleic ether is removed from the filtrate in the same manner as the ether in the first part of the determination. The residue is taken up with alcohol to remove wax, filtered, and the filtrate made to 100 cc. volume. An aliquot of 20 cc. (equivalent to 1 gm. of hops) is transferred to a tared beaker and evaporated and weighed as under the determination of total resins. The hard resin is estimated by difference between the total resins and soft resins."

The detection of methyl alcohol in commercial alcohol preparations, A. HELLRIGEL (*Pharm. Ztg.*, 57 (1912), No. 1, p. 7; *abs. in Chem. Ztg.*, 36 (1912), No. 21, *Repert.*, p. 102).—A portion of the sample is distilled and some of the distillate obtained is mixed with one-half its bulk by weight of burnt lime and boiled under a reflux condenser for 3 hours. The mixture is then distilled from a dry flask, which contains a thermometer, the boiling point is noted, some oxalic acid dried at 100° C. added, and the mixture kept boiling for 1 hour. On cooling, crystals of the dimethyl ester of oxalic acid, a liquid which has a boiling point of 54°, will be found deposited in the bottom of the flask.

The activities of the agricultural experiment station at Hildesheim, AUMANN (*Ber. Landw. Vers. Stat. Hildesheim*, 1911, pp. 15).—This report includes the results during 1911 in examining fertilizers, feeding stuffs, seeds, dairy products, stock feeds and condiments, and miscellaneous substances.

## METEOROLOGY—WATER.

The structure of the atmosphere in clear weather, C. J. P. CAVE (*Cambridge, England*, 1912, pp. XII+144, pls. 33, figs. 47; *rev. in Met. Ztschr.*, 29 (1912), No. 8, pp. 397, 398).—Data obtained from 200 pilot balloon ascensions at Ditcham, England, are summarized and discussed, together with the methods employed and their accuracy. "A general summary of the results obtained is given . . . in which certain types of structure in the atmosphere are recognized, and the different types are considered in their relation to the wind

at the surface, the gradient wind, and the general distribution of pressure and temperature in the region."

**Bulletin of the Mount Weather Observatory** (*U. S. Dept. Agr., Bul. Mount Weather Observ., 5 (1912). pt. 1, pp. 1-82, figs. 24*).—This number contains the following articles: Daily Changes in Temperature up to 4,000 Meters (illus.), by A. J. Henry; and Free Air Data at Mount Weather for January, February, and March, 1912 (illus.), by W. R. Blair.

**Monthly Weather Review** (*Mo. Weather Rev., 40 (1912). Nos. 7, pp. 977-1142, pls. 9; 8, pp. 1143-1292, pls. 9*).—In addition to the usual climatological summaries, weather forecasts and warnings for July and August, 1912, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology, a condensed climatological summary, and climatological tables and charts, these numbers contain the following special papers:

No. 7.—The Richmond Tornado of May 12, 1912, by J. H. Kimball; Tornado at Grand Rapids, Mich., by C. F. Schneider; Local Storms in July, 1912, by U. G. Purssell, C. J. Root, and V. H. Church; A Phenomenally Heavy Rain at Alton, Ill., by M. W. Hayes; Severe Thunder Storm at Minneapolis, Minn., July 12, 1912, by M. R. Hovde; Wisconsin River Flood, July, 1912, by J. H. Spencer; Flood in Cherry Creek Basin, Colorado, July 14, 1912, by P. McDonough; Excessive Rains in Louisiana, by E. D. Coberly; Storm of July 19, 1912, Salt Lake City, Utah; Storm at Mazuma, Nev., by H. F. Alps; Recent Storms at Murray, Utah, by R. C. Towler; The Relation Between Light Precipitation and "Alkali," by R. A. Hart; Notes on the Rivers of the Sacramento and Lower San Joaquin Watersheds during July, 1912, by N. R. Taylor; Frost Fighting at Pomona, by J. E. Adamson; Variation of Rainfall with Altitude, by A. G. McAdie (see p. 817); Reconnoissance of the Deschutes River in July, 1912, by J. H. Lewis; Occurrence of Precipitation on Change of Wind to North with Approach of a High Barometer, by D. F. Manning; and Climate of Prince Georges County, Md.

No. 8.—The Avalon Tornado of August 21, 1912, by J. H. Kimball; Mammato-cumulus Clouds, by J. H. Kimball; Heavy Rainfall at Dubuque, Iowa, by J. H. Spencer; August, 1912. Flood of the Wisconsin River, by J. H. Spencer; Electric Induction by Clouds during Thunderstorms, by H. A. Frise; A Severe Storm at Concordia, Kans., by J. W. Byram; Tornado at Booneville, Ark., by H. F. Alciatore; Cause of the Equable Temperature Conditions at New Orleans, La., by E. D. Coberly; Notes on the Rivers of the Sacramento and Lower San Joaquin Watersheds during August, 1912, by N. R. Taylor; Notes on Streams and Weather of the Upper San Joaquin Watershed, by W. E. Bonnett; Note on Formation of a Cloud during Forest Fire, by F. H. Carpenter; and Dog Days.

The action of forests on late frosts, E. CUIF (*Ann. Sci. Agron., 4. ser., 1 (1912), 11, No. 3, pp. 161-166; abs. in Rev. Sci. [Paris], 50 (1912), 11, No. 24, pp. 755, 756*).—Data regarding temperature conditions in forests and in the open are cited to show that forests lower the maxima and raise the minima of temperature, reducing the damage from late frosts.

Distribution of the temperature at various heights from the ground during frosts, G. KOSLOVSKII (*Khozâistvo, 7 (1912), No. 25, pp. 841, 842; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 9, p. 1926*).—Observations during a night of heavy frost showed the lowest temperature at a height of 2 ft. 4 in. above the ground. At 4 ft. 8 in. the temperature was almost twice as high and at 14 ft. the temperature was but slightly or not at all below freezing. "For this reason trees in flower suffered very little, less than shrubs; the leaves of the vine were scorched precisely at a height between 2 ft. 4 in. and 3 ft. 3 in."

**Variation of rainfall with altitude.** A. G. MCADIE (*Mo. Weather Rev.*, 40 (1912), No. 7, p. 1107).—Observations at different elevations on the San Joaquin River, California, are summarized. These show that the average increase in rainfall up to 3,500 ft. was at the rate of 1 in. per hundred feet. The average increase up to 2,441 ft. was at the rate of 0.73 in. per hundred feet, while the average rate of increase in the level between 2,441 and 3,500 ft. was at the rate of 1.45 in.

**Rainfall in tropical areas and variations observed corresponding to the changes in the moon's phases,** F. WHITE (*Proc. Rhodesia Sci. Assoc.*, 11 (1911), pt. 1, pp. 57-86, figs. 6).—A study of rainfall data at three places (Bulawayo, Selukwe, and Salisbury) lying within the tropics in South Africa, here presented in detail, are stated to indicate a decided correlation between rainfall and lunar phases. "The summaries of the totals of the three stations for each of the seven days of each lunar period give 6.44 in. of rainfall, which is the minimum, precisely at the time of the full moon, and 26.46 in. as the maximum, which falls one day after the day of the new moon. The next highest figure, 26.29 in., follows the day of the last quarter."

**Measurements of evaporation from lakes.** K. FISCHER (*Met. Ztschr.*, 29 (1912), No. 8, pp. 366-372, fig. 1).—Observations on lakes in the Alps and in Prussia are reported and discussed, particularly with reference to the accuracy of the methods used.

**Evaporation in Egypt and the Sudan,** J. I. CRAIG (*Cairo Sci. Jour.*, 6 (1912), No. 68, pp. 103-107; *abs. in Met. Ztschr.*, 29 (1912), No. 8, pp. 392, 393).—Data for measurements of evaporation in 6 districts of Egypt and the Sudan are summarized and the accuracy of the observations is discussed.

**The water supply of Indiana** (*Ann. Rpt. Ind. Bd. Health*, 29 (1910), pp. 349-356, figs. 4).—The results of examinations of a large number of samples of water collected by health officers are presented graphically and briefly discussed.

The results show that the public water supplies were superior in character to the private supplies. Of the public water supplies examined 129 were from deep wells, 24 from shallow wells, 16 from streams, 14 from ponds or lakes, 7 from springs, and 1 from a cistern. The private supplies were drawn from 212 deep wells, 357 shallow wells, 24 springs, 31 cisterns, 3 streams, and 3 ponds. Of the 341 samples of deep well waters examined, 303 were good, 18 were bad, and 20 were of doubtful quality. Of the 381 shallow well samples 185 were of good quality, 158 bad, and 38 of doubtful quality. Of the 19 samples of stream waters examined 10 were good, 6 bad, and 3 doubtful. Of 17 samples of pond water 14 were good and 3 doubtful. Of 31 samples of spring water analyzed 22 were good, 2 bad, and 7 doubtful. Of 32 samples of cistern water 20 were of good quality, 11 bad, and 1 doubtful. A large percentage of the waters used by families in which a case of typhoid fever had occurred were unqualifiedly bad.

**Sewage sludge disposal,** W. B. RUGGLES (*Manfrs. Rec.*, 62 (1912), No. 15, p. 51).—This article briefly describes what is being done in a number of places in England in the way of utilizing sewage sludge as a fertilizer.

It is stated that "there is no question at the present time of the value of the sludge as a fertilizer. This has been amply proved, and there is a constantly increasing demand for it at prices ranging from \$5 per ton to \$12, depending on the amount of nitrogen contained.

"Where lime is used as a precipitant, part of the nitrogen is converted into ammonia and is lost, so that such sludge will only contain about 1.5 per cent of nitrogen, leaving a value of about \$6 per ton, while sludge precipitated by sulphuric acid or sulphates will contain at least 2.5 per cent, with a value of \$10 per ton or more.

"The cost of producing such fertilizer, including pressing the sludge, drying, grinding, and bagging, will vary somewhat with the size of the plant and quantity produced, but should not cost over \$1.75 per ton at any plant producing 10 tons or more per day."

### SOILS—FERTILIZERS.

What the States are doing toward the conservation and improvement of soil fertility, T. N. CARVER (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 24 (1912), Sect. XIb, pp. 47-57, fig. 1*).—This is an address delivered before the Eighth International Congress of Applied Chemistry in which the author gives an account of the activities of the various States in the promotion of irrigation and drainage work, the prevention of soil erosion by forestation and other means, and the direct improvement and conservation of the fertility of the soil by scientific methods of culture.

The author maintains that "the only legitimate purpose of soil improvement and conservation is to increase the product per man, and a larger product per acre is desirable only when it gives us a larger product per man." It is a thing to be shunned "if it is to be secured by those forms of intensive culture which are forced upon overpopulated countries where labor is abundant and cheap and land scarce and dear." Judged by the standard of utilizing labor so as to secure the largest income per man or per family, and thus to live upon as high an economic plane as possible, "our system of agricultural education makes an excellent showing as compared with that of other countries, though there is much to be done yet."

Recent advances in agricultural science.—The fertility of the soil, A. D. HALL (*London: Roy. Inst. Great Brit., 1912, pp. 9; Nature [London], 89 (1912), No. 2234, pp. 648-651; Sci. Amer. Sup., 74 (1912), No. 1920, pp. 246, 247*).—This is an address delivered before the Royal Institution of Great Britain in which the author outlines three stages in the development of the agriculture of a country, namely, (1) the period of exploitation, (2) the conservative period, and (3) the period of intensive agriculture, illustrating each by farming systems in vogue in different countries and tracing the inner history of these three stages of agriculture by the records of certain experimental plats at Rothamsted.

It is shown that in maintaining the level of intensive production the losses, particularly that of nitrogen, due to bacteria in the soil, are increased out of all proportion until there is recovered in the crop only about one-fourth of the nitrogen applied in the manure. Hence, there must be returned to the soil not merely the nitrogen contained in the extra amount of crop produced but several times that amount to repair the waste, and still greater amounts when the fertility and the production are increased.

In the author's opinion, therefore, the important problem in intensive agriculture to-day is the reduction of this waste of nitrogen due to bacterial action. He points out, on the basis of the work of Russell and Hutchinson at Rothamsted (*E. S. R., 22, p. 121*), that by putting the soil through various processes of partial sterilization, such as heating or treatment with antiseptics like chloroform or toluene, "we can eliminate certain organisms which keep in check the useful bacteria in the soil, that is, the bacteria which break down the nitrogen compounds to the state of ammonia, a form assimilable by plants. . . . At present the processes have not been extended to the open field, but progress is being made in that direction, and give some promise of a method by which ultimately the unseen fauna and flora of the soil will be domesticated, the useful races encouraged, and the noxious repressed."

Some problems in soil fertility, G. SEVERANCE (*Washington Sta. Popular Bul.* 44, pp. 8).—This is a brief, popular discussion of various factors influencing the fertility of soils, with particular reference to Washington soils.

A case of soil infertility due to bad texture and lack of lime, J. A. HANLEY (*Jour. Bd. Agr. [London]*, 19 (1912), No. 5, pp. 375-378).—With a view to determining the cause of the infertile condition of the soil of a portion of a field near Luton, Bedfordshire, the author made physical analyses of the soil and determined its calcium carbonate content. The results showed that the infertile condition was due to the unfriable nature of the soil, caused by its low calcium carbonate content, the samples analyzed containing 0.28 per cent of this constituent in both surface and subsoil, as compared with 2 per cent for the surface soil and 1 per cent for the subsoil of samples of the productive soil of the field.

Reference is also made to analyses of samples of soil of the Geescroft field at Rothamsted and of a similar soil at Hamsey Green, Surrey, both of which showed a low calcium carbonate content and were in a very poor state of tilth.

Studies on soil physics.—II. The permeability of an ideal soil to air and water, W. H. GREEN and G. A. AMPT (*Jour. Agr. Sci.*, 5 (1912), No. 1, pp. 1-26, pl. 1, figs. 10).—The authors review previous investigations on the subject by others, particularly the work of Slichter and of King (E. S. R., 11, pp. 519, 523), and in continuation of earlier work (E. S. R., 25, p. 620) report measurements of the permeability of glass beads and quartz sand to air and to water. An elutriation method and apparatus for grading the particles are described.

The permeabilities of the glass beads, both to air and water, were from 50 to 85 per cent greater than the value calculated from Slichter's formula. This is held to be due to Slichter's method "of considering each soil capillary as if it were a double triangular-shaped pore with a partition down the center instead of as an undivided more or less rhomboidal pore at its narrowest part." When this condition was fulfilled, the permeability of the glass beads approached the value calculated in the formula.

The permeability of the sand, although subject to a rather large percentage error, was on an average "9.45 for the permeability to air . . . and 9.31 for the permeability to water. . . . The obvious explanation (of this less perfect material agreeing more perfectly with the theoretical formula) is that the angular shapes of the particles do practically have the effect of dividing the pore into two triangular passages as assumed in the formula."

The general conclusion, therefore, is that "the formula  $\eta P = 10.2 \frac{d^2}{k}$  holds quantitatively for variations of the pore space and of the diameters of the soil particles. This will be so whether the permeating fluid be air or water, provided that the actual sizes of the soil particles are unaffected by the presence of water.

"With this factor taken into account it is, therefore, legitimate to consider a soil as statistically composed of a bundle of capillary tubes when discussing the movements of air and water through it."

Observations on liquids circulating in cultivated soils, G. GOLÀ (*Ann. R. Accad. Agr. Torino*, 54 (1911), pp. 33-67, fig. 1).—This article has been noted from another source (E. S. R., 26, p. 422).

The movement of water in irrigated soils, J. A. WIDTSOE and W. W. McLAUGHLIN (*Utah Sta. Bul.* 115, pp. 195-268, figs. 8).—This is a detailed report of a series of irrigation investigations conducted by the Utah Station in cooperation with this Office, and reports a study of the mutual relationships of water, soils, and crops under cropped field conditions, the work having been partly reported upon in previous publications (E. S. R., 22, p. 425). The ex-

periments were made on a deep soil of uniform physical and chemical composition at the experiment farm at Greenville. The irrigation water used contained less than 375 parts per million of dissolved substances.

Summarizing the results of the work, the authors conclude that the maximum amount of water held by the soil in question against gravity under field conditions was about 24 per cent (on a dry basis) and the minimum amount above 8 per cent except that the soil of the top foot dried out to 5.64 per cent.

"Irrigation was needed whenever the soil moisture fell below 12 per cent.

"The degree to which water may be removed from the soil depends upon the kind of crop grown; and the degree of dryness at which irrigation is necessary likewise depends, in a limited measure, upon the kind of crop.

"Soil water was abstracted from below the depths of root penetration.

"Water applied in irrigation, whether of large or small amount, penetrated in the soil below the depth reached by augers, 8 ft. long.

"The percentage of soil water soon after an irrigation was invariably largest in the top foot, and became smaller with increasing soil depth.

"Under given conditions of soil, crop, water, and time after irrigation, the distribution of the soil water is always the same. This implies the operation of a definite law governing the distribution of soil water.

"It would seem that the water added to a soil of the Greenville type, up to about 12.75 per cent on the dry basis, is held very firmly by the soil, and can move only with great difficulty. Water added above this point moves freely in obedience to capillary laws.

"It is suggested that the point below which capillary movements become sluggish be called the point of lento-capillarity.

"It would appear that water added to a soil above the point of lento-capillarity is distributed through the soil inversely with the distance from the source of supply, which is the zone of wettest soil. This law of distribution takes the form of the formula of the equilateral hyperbola.

"Plants may use the soil water below the point of lento-capillarity, but not readily.

"Plants can not use any of the true hygroscopic water. The hygroscopic capacity depends largely on the amount of clay or other colloidal substances found in the soil.

"In soils of the Greenville type, under field conditions, there are several critical soil water points: The maximum capillary water content, which is about 24 per cent; the optimum water content, to a depth of 8 ft., about 18 per cent; the lento-capillary point, about 12.75 per cent; and the hygroscopic capacity about 6 per cent.

"In furrow irrigation, the amounts of water under row and furrow are unequal near the surface, but become more uniform at lower soil depths. This indicates that the lateral movement of soil water increases with the depth.

"Evaporation from bare soils is large, but may be checked by early and thorough cultivation. On the Greenville farm, under average conditions on cropped plats, a little more water was taken from the soil by evaporation than by transpiration. The rate of loss of soil moisture from cropped soils depends on a number of factors.

"The removal of water from the soil by transpiration varies with the ease with which water may be obtained, that is with the amount of water in the soil at the beginning of an experiment. It would appear that the rate of loss of soil water varies directly with the cube root of the percentage of water in the soil above the point of lento-capillarity.

"The loss of soil water increases steadily with the time after irrigation. Moisture conserving methods should, therefore, be applied early.

"The relation of meteorological conditions to the rate of loss of soil water is important, but somewhat obscure. Temperature is probably the most important factor; then sunshine; and then relative humidity.

"The larger the percentage of water in the first foot, the more rapidly is water drawn from the soil. This is probably due in part to the larger development of plant roots near the surface.

"Early maturing crops cause the highest rate of loss of soil moisture. Different crops leave different percentages of water in the soil at the time of harvesting.

"The rate of loss of soil water varies with the age of the crop. Less water is used during the early and late periods than during the middle one.

"When water is abstracted from a soil, the loss is felt by every foot to the depth reached by the augers.

"When a practical irrigator declared irrigation to be necessary, the soil was found to contain from year to year about 13 per cent of water."

**The biochemical relation of phosphoric acid in the soil,** MÜLLER (*Mitt. Dent. Landw. Gesell.*, 27 (1912), No. 33, pp. 470, 472, 473).—This is a review of the work of Stoklasa (E. S. R., 25, p. 621) on this subject.

**Soil conditions and plant growth.** E. J. RUSSELL (*New York, Bombay, and Calcutta, 1912, pp. VIII+168, figs. 9*).—This treatise by the former soil chemist and present director of the Rothamsted Experimental Station, is one of the series of monographs on biochemistry edited by R. H. A. Plimmer and F. G. Hopkins. Its purpose is to give a concise and orderly account of the present knowledge of the soil as a medium for plant life. It is a comprehensive critical survey of the literature of this subject, and while presenting the gist of the more important and fundamental contributions to the knowledge of the subject, points out what has really been demonstrated and in what directions further investigation is necessary. The book is therefore of special value to the investigator.

The first chapter is historical and introductory, others deal with the requirements of plants, the constitution of the soil, the carbon and nitrogen cycles in the soil, the biological conditions in the soil, the soil in relation to plant growth, and soil analysis and its interpretation. An appendix gives methods of soil analysis and a select bibliography of the subject.

**Some observations on the effect of soil aeration on plant growth,** C. HUNTER (*Proc. Univ. Durham Phil. Soc.*, 4 (1911-12), No. 4, pp. 183-186, pls. 2).—Observations on the growth of sunflowers, peas, wheat, and cress in soils of five different textures with and without artificial aeration are reported. Observations were also made on the varying moisture and bacterial contents and on the resistance of the soils to the movement of air.

The results indicated an optimum amount of circulation of air in the soils for different kinds of plants. "The circulation of the air in the soil affects the development of the root system and through that the development of the subaerial portions of a plant. The production of artificial air currents in the soil appears to be beneficial to plant growth. This point is at present undergoing further investigation."

**The relation of different systems of crop rotation to humus and associated plant food,** G. W. WALKER (*Minnesota Sta. Bul.* 128, pp. 165-186).—The author reviews investigations by others on the physical and chemical properties of, and methods of determining, humus and in continuation of previous work by Hays (E. S. R., 20, p. 435), reports a study from 1895 to 1905 of the changes produced in humus and of the proportion of the total nitrogen, phosphoric acid, and potash associated with the humus in soil of plats under known cropping and fertilizer-systems. The term humus is used by the author to

designate that portion of the organic matter of the soil soluble in dilute solution of ammonia and sodium hydroxid after removal of the lime and magnesia by treatment with dilute hydrochloric acid.

The centrifugal method was used in making the determinations, a preliminary comparison of this and the official method having shown that by using the centrifuge the time was considerably shortened and the results were equally accurate. The humus ash was a little lower for the centrifugal method.

Summarizing his results the author concludes that "continuous cropping to corn, mangels, and wheat causes a depletion of humus; on the other hand, field peas increase the amount of humus. Generally rotation of crops increases the amount of humus, the increase being greatest when clover is plowed under. There is a fair agreement in regard to the direction of the changes in humus as compared with the changes in total nitrogen and humus-nitrogen; continuous cropping causing depletion, and rotation of crops an increase.

"Except in the case of wheat, no marked decrease in total phosphoric acid has occurred in the continuously cropped plats. Generally, under systems of crop rotation, the plats have maintained the total phosphoric acid content for the 10-year period. The humus-phosphoric acid has decreased in all the plats, with one exception, both under continuous cropping and systems of crop rotation; the depletion being greater in the continuously cropped plats.

"No definite conclusions can be drawn from the results obtained for total potash. However, a much greater depletion occurs in the case of wheat than in the other continuously cropped plats. In general, a marked decrease in humus-potash has occurred in the continuously cropped plats, as compared with the rotation plats. In the rotation plats a decrease of humus-potash has occurred in all the plats, except those which received applications of stable manure. The relatively large proportions of nitrogen, phosphoric acid, and potash associated with the humus indicate the great importance and value of the latter as a source of plant food."

The distribution and activities of bacteria in soils of the arid region, C. B. LIPMAN (*Univ. Cal. Pubs. Agr. Sci.*, 1 (1912), No. 1, pp. 20).—Recognizing the important differences in physical and chemical characteristics between soils of humid and those of arid regions as shown by the work of Hilgard and Loughbridge, the author undertook a study of the ammonifying, nitrifying, and nitrogen-fixing powers of different soil types of the arid region of California as compared with those of humid sections. The determinations were made for every foot of soil to a depth of 12 ft. A modified Remy solution method was used, since the direct soil culture method was not considered feasible for obtaining in an uncontaminated condition such large amounts of soil as these experiments required. The samples of soil were obtained "from a hole 12 ft. in depth with at least one vertical wall, the latter when sterilized being sampled."

It was found that these soils, which are considered typical of the arid region, showed ammonifying powers at all depths studied but generally most vigorous in the first 6 or 8 feet. "In one case ammonification was noted in soil from a depth of 15 ft., or adjoining the water-table."

Nitrification occurred commonly down to a depth of 5 to 6 ft. In one case soil from the 8 ft. depth showed a vigorous nitrifying power. There was no nitrogen fixation through *Azotobacter* "below 2 ft. in the soil usually, but [it] has been found in some soils at 3 ft. and in one soil down to 4 ft. Many soils in the arid region, otherwise favorably constituted, do not contain *Azotobacter* organisms."

In general, the lower layers of arid soils differed markedly from those of humid regions in ammonification and nitrification and to a less extent in nitro-

gen fixation. These characteristics "help to explain the favorable physical and chemical constitution of the soil and also the deep rooting of plants so characteristic of the arid regions."

**The law of minimum**, I. POUGET and D. CHOUCHAK (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 4, pp. 303-306, figs. 2).—Referring to an article by P. Mazé noted elsewhere (E. S. R., 27, p. 721), the authors offer what is claimed to be strong experimental evidence in favor of a law of minimum which, it is claimed, plays an important part in large scale cultivation, especially in dry soils.

**A contribution to the knowledge of the black cotton soils of India**, W. H. HARRISON and M. R. R. AMASWAMI SIVAN (*Mem. Dept. Agr. India, Chem. Ser.*, 2 (1912), No. 5, pp. 261-280, pls. 4; *abs. in Jour. Soc. Chem. Indus.*; 31 (1912), No. 20, pp. 999, 1000).—The authors review previous investigations on the subject by Leather (E. S. R., 10, p. 421) and by Annett (E. S. R., 23, p. 316), and report studies of the geological distribution of the regur or black cotton soils of India and the chemical and physical characteristics of the soil particles, with a view of determining the cause of the black color of the soils.

It is concluded from the results that "the black cotton soils of India are not derived from any specific geological formation, such as trap, but are formed from many diverse formations and generally, when not alluvial, bear a close relationship to the underlying rocks.

"Titaniferous magnetite is not a constant factor in the regur soils of the Madras Presidency, and, even when found, the amount is small, but its presence in quantity is characteristic of the soils of the trap area. It can not, therefore, be looked upon as the cause of either the color or the physical properties of these soils, but only as a modifying agent.

"The color and peculiar physical properties of black cotton soils are associated with the compound particles of low specific gravity, which are found in all these soils.

"Two classes of substances have been recognized as conferring the color and physical properties. One is probably a colloidal hydrated double iron and aluminum silicate, which is mainly concerned with the formation of compound particles and which possesses, in a modified form, the properties of ordinary clay. The other is organic in character and may possibly be an organic compound of iron and aluminum."

**The soils of Webster County**, A. M. PETER and S. C. JONES (*Kentucky Sta. Bul.* 162, pp. 135-169, pl. 1).—This bulletin, which is based on work done in cooperation with the Kentucky Geological Survey, reports a survey with map of the soil types of the county, including mechanical and chemical analyses of typical samples and pot experiments with a soil similar to the upland type of the county, to determine the fertilizer and crop adaptation.

The area is typical of the western coal field of Kentucky, including about 4,500 square miles or about one-eighth of the total area of the State. The soil types established are the yellow silt loam (hilly), the yellow silt loam (undulating), gray silt loam, gray clay loam, and a dark-brown clay loam covering, respectively, 36.1, 27.3, 25.3, 8.1, and 3.2 per cent of the area.

The results of preliminary pot fertilizer tests seem to indicate on the whole that "phosphorus decidedly increased the yields of wheat, oats, and clover, but not that of tobacco; that nitrogen decidedly increased the yields of wheat, oats and tobacco, but not that of clover; that potassium moderately increased the yields of wheat and oats and slightly increased that of clover, but did not have a marked effect on that of tobacco. Rock phosphate, used alone, gave consistent gains, except with tobacco. Used with manure, however, its effect seems to have been negative, contrary to the usual teaching. Limestone pro-

duced moderate increase with oats and clover and with tobacco following clover. Used with phosphorus on clover there was a decided increase over the pot where phosphorus alone was tried."

**Protocol of the sixty-eighth session of the Central Moor Commission** (*Protokoll der 68. Sitzung der Central-Moor-Commission. Berlin, 1912, pp. 258, pls. 2, fig. 1*).—This is a detailed report of the proceedings of this commission at its session from February 29 to March 2, 1912. Reports are given as to the progress made by the various local associations in the colonization of these lands and in the production of different crops and methods of cultivation and fertilization. A report of the work of the moor experiment station, consisting principally of studies in crop adaptation and methods of cultivation and fertilization of the soils, is included.

**Report of the chemist, P. L. GILE** (*Porto Rico Sta. Rpt. 1911, pp. 15-23*).—This is a brief report of progress in the examination of bat guanos (see p. 825), study of the effect of the lime-magnesia ratio in plant growth, effect of calcareous soils on the composition and health of plants, and the treatment of "sick" red clay soils.

**The atmosphere as a raw material in fertilizer production** (*Manufrs. Rec., 62 (1912), No. 11, pp. 48, 49*).—This article refers to the installation of a plant for the manufacture of calcium nitrate from the nitrogen of the air at Nitrolee, S. C., and to a proposed plant for the same purpose in Alabama. It also discusses briefly the present status of the manufacture of nitrogen compounds from the air.

**Supposed loss of nitrogen in calcium cyanamid (nitrolime), G. LIBERI** (*Ann. R. Staz. Chim. Agr. Sper. Roma, 2. ser., 5 (1911), pp. 163-177; abs. in Jour. Soc. Chem. Indus., 31 (1912), No. 18, p. 890*).—Exposure for 50 days to severe and constantly changing atmospheric conditions resulted in a loss of only about 3 per cent of the total nitrogen of the cyanamid.

**Instability of the cyanamid nitrogen in calcium cyanamid (nitrolime), G. LIBERI** (*Ann. R. Staz. Chim. Agr. Sper. Roma, 2. ser., 5 (1911), pp. 179-197, figs. 2; abs. in Jour. Soc. Chem. Indus., 31 (1912), No. 18, pp. 890, 891*).—Loss of nitrogen from crude calcium cyanamid was greatest in damp air and but slight in dry air. The nitrogen of the cyanamid completely disappeared in 1 and 5 per cent solutions, rapidly at first, more slowly afterwards. The loss was more rapid in the stronger solution. The dicyandiamid nitrogen increased rapidly at first and then gradually declined. No ammonium compounds were found in either solution.

**A new artificial manure** (*Queensland Agr. Jour., 29 (1912), No. 4, pp. 315, 316*).—Brief reference is here made to a British consular report from Christiania, Norway, calling attention to a by-product of the manufacture of nitrate of lime at Notodden, Norway, known as biphosphate and containing 26 per cent of phosphoric acid, 92 per cent of which is citrate-soluble, and 23.8 per cent of nitrate of lime.

**The principal catalytic fertilizers, E. MIÈGE** (*Jour. Agr. Prat., n. ser., 24 (1912), No. 32, pp. 171-173*).—A brief résumé is given of results of experiments by various investigators on the fertilizing effect of compounds of manganese, boron, aluminum, zinc, uranium, copper, lithium, bromin, fluorin, and iodin. The author concludes that the results obtained in experiments with these compounds emphasize the insufficiency of our knowledge of the physiology and chemistry of plants and indicate enormous possibilities in the way of extending and improving methods of fertilizing the soil.

**[The toleration of coffee and of cacao plants for sodium chlorid], J. KUIJPER** (*Dept. Landb. Suriname Verslag, 1911, pp. 11, 12*).—In view of the fact that the water available for sprinkling and also for irrigation purposes

during dry seasons in Dutch Guiana contains rather large amounts of sodium chlorid, experiments were made with coffee and cacao plants grown on red sandy soils in plats and in pots, respectively, to determine the amount of this salt which these plants would tolerate.

In case of the coffee plants, it was found that a concentration of 0.1 per cent showed a slight discoloration of the leaves in only one case, whereas the use of water containing 0.3 per cent caused considerable injury, as was manifested in the shedding of some of the leaves. A 1 per cent solution killed the weaker plants and caused some discoloration of the leaves of the more vigorous plants.

In case of the cacao plants, it was found that the 2, 3, and 4 per cent solutions had a direct injurious effect. The leaves became markedly discolored and dropped off. There was only a very slight injury in case of the 1 per cent solution. The 0.5 per cent solution did not injure the plants to any appreciable extent.

The availability of the nitrogen and phosphoric acid in bat guanos, P. L. GILE (*Porto Rico Sta. Rpt. 1911, pp. 16-18*).—Analyses of 18 samples of Porto Rican bat guanos are reported and reference is made to plat experiments to correlate their actual relative fertilizing value with the chemical analyses. These samples showed nitrogen varying from 0.4 to 5.49 per cent and phosphoric acid from 4.35 to 26.18 per cent.

Regarding the fertilizer value of pond mud, P. KOSOVICH (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 13 (1912), No. 4, pp. 537-549*).—A comparative study of the composition of mud of a pond situated near Orel, Russia, and of the soil of the surrounding district is reported.

The results show that the mud analyzed did not have a high fertilizer value, and that its constitution was similar to that of the local soils. The calcium carbonate and the magnesium carbonate contents of the mud were relatively high (about 3 per cent combined), notwithstanding the almost entire absence of these constituents in the soil, thus indicating that the pond water was not derived alone from the surface water but also from waters of the calcareous loess substratum.

The high citric-acid-soluble character of the phosphoric acid of the mud was significant, 0.15 per cent, or approximately ten times that of the soil, being soluble, notwithstanding the fact that the total phosphoric acid content of the mud was only slightly higher than that of the soil (0.32 per cent and 0.298 per cent, respectively). The potash content soluble in 10 per cent hydrochloric acid was 0.44 per cent for the mud as compared with 0.24 per cent for the soil. The amount of water-soluble constituents of the mud was relatively high, being 0.36 per cent before, and 0.23 per cent after, ignition. The nitrogen content of the mud was 0.27 per cent as compared with 0.345 per cent for the soil.

Guadeloupe's use of fertilizers, F. T. F. DUMONT (*Daily Cons. and Trade Rpts. [U. S.], 15 (1912), No. 256, pp. 556, 557*).—Statistics of the fertilizer trade in Guadeloupe are briefly summarized. It is shown that in 1911 4,360 metric tons of fertilizer, valued at \$293,769, were used, or an average of 109 lbs. per acre of cultivated area. These fertilizers were imported almost exclusively from France and Great Britain.

Fertilizers in Russia (*Bd. Trade Jour. [London], 78 (1912), No. 815, p. 74; Handelsmuseum, 27 (1912), No. 24, p. 350; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 9, pp. 1956, 1957*).—It is stated that there has recently been a substantial growth in the consumption of chemical fertilizers in Russia, which may be attributed either to the agricultural progress of the country or to partial exhaustion of the high fertility of some of the soils, black soils in particular. The fertilizers are now largely

imported, the imports nearly trebling in the 5 years, 1907 to 1911. In the latter year the imports amounted to 362,629 tons valued at \$3,675,060.

### AGRICULTURAL BOTANY.

The influence of the concentration of dissolved nutritive substances on their absorption by plants, I. POUGET and D. CHOUCIAK (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 25, pp. 1709-1711, fig. 1).—Continuing previous work regarding the relations between the concentration of dissolved nutritive substances and their absorption and assimilation by plants (E. S. R., 24, p. 423; 25, p. 127), the authors make the following statements:

At very low concentrations (in case of phosphoric acid less than 0.1 mg. per liter) absorption of the solute does not take place, but such substance tends rather to pass from the cells containing it into the solvent in either mineral or organic form. If, however, the concentration of the solute is continuously raised, absorption begins at a certain point (a) and its rate increases faster than does that of concentration. At a second point (b) the two rates become proportional and remain so to a third point (c) beyond which concentration increases faster than absorption, the latter now being regulated not by concentration but by utilization of that solute by the cell. The general course of these changes depends upon the particular substance absorbed, the state of the plant, and the vegetative period in which it is tested.

It was found that in very dilute solutions the absorption of nutritive substances was much greater than that of the water. The above results are held to show (1) that soil water, in spite of its low content of the elements of fertility, ought to play an important rôle in the elaboration of crops; (2) that is, if the concentrations of all the elements necessary to the plant are higher than the point (c), nutrition goes on normally and the crop does not depend upon climatic conditions; but (3) if the concentration of such elements (or even only of one, according to the law of minimum) is below that point the crop returns will depend upon the concentration of that element.

The influence of radio-active mineral on the germination and on the growth of wheat, A. J. EWART (*Jour. Dept. Agr. Victoria*, 10 (1912), No. 7, pp. 417-421).—The author tested the influence of radio-active mineral, known to accelerate germination of cereals, on the development of bacteria and on the growth of wheat when applied as a manure. It was found that in the first case a distinctly retardative action is exercised which becomes more pronounced with longer exposures, and that in the second any early stimulating effect becomes converted into an injurious one on prolonged contact. He concludes that, in practicable applications, radio-active material does not appear to have any direct value for the growth of wheat.

The action of uranium on the vegetable cell, C. ACQUA (*Arch. Farmacol. Sper. e Sci. Aff.*, 14 (1912), No. 2, pp. 81-84).—Pursuant to previous investigations on the influence of radio-active substances on the life processes of plants (E. S. R., 24, pp. 230, 531) the author now reports that uranium can be absorbed by certain cells of higher plants, in which it hinders karyokinesis, checking cell division. This influence is said to be considerable in the tissues of the root system, but much less so in the stem tissues on account of less ready absorption there. Thorium and manganese are said to show somewhat analogous properties, but the latter in much less degree and in a way more compatible with the development of the plant.

The influence of narcotics on the chemical composition of plants.—I, The chemical behavior of plants in acetylene atmosphere, V. GRAFE and O. RICHTER (*Sitzber. K. Akad. Wiss. [Vienna]*, *Math. Naturw. Kl.*, 120 (1911),

*I*, No. 10, pp. 1187-1229).—This report, in continuation of work on the influence of gases on plants (E. S. R., 25, p. 434), gives the results obtained by the authors in their study on the development and chemical products of potato, flax, and various leguminous plants grown in dilute acetylene gas.

Acetylene in various dilutions (from 0.69 to 0.038 per cent by volume) was found to give marked contrasts in development as compared with those of the control plants. For example, in dilute acetylene there was shown more glycerin and fatty acid, but less sugar, fat, and amido compounds than in plants grown in pure air. Corresponding to these chemical conditions and in part explained by them are noted such physiological differences as heightening of turgor, bursting of seedlings, checking of growth in length, augmentation of that in thickness, etc.

A bibliography is given.

**The influence of ultraviolet rays on higher plants**, A. J. KLUYVER (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl.*, 120 (1911), I, No. 10, pp. 1137-1170, pl. 1).—After reviewing briefly similar studies by other investigators, the author reports on his own experiments with ultraviolet rays from the mercury vapor lamp on various plants in regard to the effect of these short wave lengths on the life of the cells and on their coloring matters and starch.

It is said to have been found that several higher plants are injuriously affected by the mercury vapor light, this effect being attributed mainly to radiations of shorter wave length than  $300\mu$ , and being prevented by interposition of glass plates of 0.2 mm. thickness, which are known to absorb nearly all such short waves. It is held that such short solar rays are absorbed by the atmosphere, rendering artificial protection to these plants unnecessary. The injurious effects of waves longer than  $300\mu$  are said to be limited in case of leaves to the epidermis, but sometimes to extend more deeply in case of stems and roots.

Anthocyanin appears, in general, to be not very sensitive to ultraviolet rays, being removed only from the lower leaf surface of *Begonia discolor* and that simultaneously with the death of the epidermal cells. Chlorophyll is little, if at all, affected by the longer waves, which alone are able to penetrate to the parenchymatous cells. In isolated cases (*Nerium oleander* and older needles of *Taxus baccata*) the cuticle protected even the epidermal cells from the injurious action of the shorter waves. Leaves of *Mimosa pudica* showed stimulation response to the ultraviolet rays. Destructive changes are said to have been produced in the woody walls of certain cells, and starch is said to show a decrease on exposure to these shorter wave lengths.

**The influence of light on the flowering of Japanese hops and hemp**, J. TOURNOIS (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 4, pp. 297-300).—The author reports further experiments (E. S. R., 26, p. 432) with *Humulus japonicus* and *Cannabis sativa* in regard to their time and mode of flowering, in the present cases as related to differences in illumination.

Plantings of seeds were made on January 8 and 28, and the plants obtained from each group showed, as in previous experiments, an early and a late flowering period. The precocity of flowering in this case was augmented in correspondence with early planting and the weaker illumination of the winter days. Plants from seeds sown late in April and also those from sowings early in June (normal) and grown in darkness from 8 a. m. to 2 p. m. daily, flowered much more precociously than did plants normally illuminated but otherwise similarly treated.

The sexual anomalies previously noted are said to have been more accentuated in plants obtained from the earlier winter seedlings made in the present

series of experiments. Decreased illumination is held to be an important factor in all these anomalies.

**The relations between oxidation ferments and respiration in plants**, E. W. SCHMIDT (*Naturw. Wechschr.*, 26 (1911), No. 17, pp. 257-264; *abs. in Bot. Centbl.*, 119 (1912), No. 20, pp. 492, 493).—This is a critical review of recent articles on respiratory ferments, etc., particularly those of W. Palladin and his school.

**Tannin content and starch formation in woody growths**, A. RENVALL (*Bot. Centbl., Beihefte*, 28 (1912), 1. Abt., No. 2, pp. 282-306).—The author made a study of numerous trees as to the relation of their tannic acid content in the winter to their development of starch in the following spring.

It was found that in those structures deficient in tannin and in those trees in which it appeared wholly wanting there was no corresponding lack of starch development in spring. From a study of the details observed the conclusion is drawn that tannin in the cases studied can have little or no significance as a transformation product, or as an agent influencing transformation, so far as starch is concerned. Further studies are promised on starch transformation in leaves which remain green during the winter.

**Some conditions influencing the fixation of nitrogen by Azotobacter and the growth of the organism**, FLORENCE A. MOCKERIDGE (*Ann. Bot. [London]*, 26 (1912), No. 103, pp. 871-887).—The author's investigations on the production of a vigorous culture of *Azotobacter* led to the following conclusions:

The presence in the medium, as a neutralizing agent, of an excess of calcium or magnesium carbonate or of basic slag, is more advantageous than that of sodium hydrate. The presence of sodium salts is unnecessary and depressing. A good growth being once obtained, the yield of nitrogen appears to be practically proportional to the food supplied. The most active fixation occurs during the first week, being thereafter depressed, apparently, by the accumulation of the products of vital activity. It appears that a proportion of 0.4 per cent of basic slag has the most beneficial effect upon the activity of the organism, 1 per cent showing a second and lower maximum. It is thought probable that the iron and manganese present in the slag exert, in addition to a neutralizing effect, tonic influences upon the organisms, these reaching maxima at 0.4 and 1 per cent, respectively.

**The formation and physiological significance of the root nodules in the Podocarpaceæ**, ETHEL R. SPRATT (*Ann. Bot. [London]*, 26 (1912), No. 103, pp. 801-814, pls. 4).—The author reports on a series of investigations made with *Podocarpus*, *Microcachrys*, *Dacrydium*, *Saxegothæa*, and *Phyllocladus*, all possessing root nodules. These nodules are claimed to be modified lateral roots, perennial and usually unbranched.

*Pseudomonas radicolica* penetrates by way of a root hair to the cortical cells of the root, where it propagates itself, infecting the meristematic tissue and stimulating the development of a nodule which, when mature, is traversed for about half its length by a small stele. Nodules of the Podocarpaceæ differ from those of all other nonleguminous plants in that there is no differentiation of a meristematic zone in the cortical tissue. Many cortical cells of root and nodule eventually become water storage cells, some containing bacteria in a quiescent state during the winter. The bacteria form a very definite zooglea in the cells, slime threads passing from cell to cell.

The bacteria isolated from the nodules of the Podocarpaceæ are found to be identical with *P. radicolica* obtained from those of the Leguminosæ, Cycadaceæ, Elæagnaceæ, *Alnus*, and *Myrica*; capable of assimilating atmospheric nitrogen; and presumably of benefit to the Podocarpaceæ.

A bibliography is given.

On well-marked aerotropic growths of *Bacillus megatherium*, J. C. JOHNSON (*Ann. Bot. [London]*, 26 (1912), No. 103, pp. 949, 950).—The author reports on his observations made for 3 years with the annual periodicity of growths of this bacterium on the dead extremities of the roots of a palm. The growths are still being watched for any gradual change from the flat films to the raised growths observed, in the hope of showing a connection between ordinary free-living bacteria and the more highly specialized fructifications of the Myxobacteriaceæ.

*Spiræa ulmaria* and its bearing on the problem of xeromorphy in marsh plants, R. H. YAPP (*Ann. Bot. [London]*, 26 (1912), No. 103, pp. 815–870, pls. 3, figs. 11).—This is a study of the xerophytic characters exhibited by meadow sweet, reviewing also the present state of knowledge in regard to swamp xerophytes, and leading to the following general conclusions:

Xeromorphy is of physiological utility to those bog and marsh plants which exhibit such characters, these being directly related to the needs imposed upon the plant by the special nature of its habitat. In each case, however, the special regulatory devices are required to meet not so much the every-day needs as the extremes, possibly even only the occasional extremes which the species has to face in nature.

An extensive bibliography is given.

Studies on the progress of plasmolysis, K. HECHT (*Beitr. Biol. Pflanz.*, 11 (1912), No. 1, pp. 137–192, pls. 2, figs. 6).—The author reports that, in studies made by him of plasmolyzed cells, he still observed, following the rupture and separation of the cytoplasmic envelope from the cell wall, numerous connecting threads of very different sizes, and also connecting with these a protoplasmic network adhering closely to the cell wall. To both these structures, it is thought, both hyaloplasm and nucleoplasm contributed, microsomes and chlorophyll grains being found together, particularly in the larger plasma masses remaining near the cell wall. The presence of this lining, it is thought, may be the result of some interaction of the plasmic components.

The part played by living cells in sap ascent, A. URSPRUNG (*Bot. Centbl. Beihefte*, 28 (1912), 1. Abt., No. 2, pp. 311–322).—The author discusses the work of several other investigators as well as some of his own on this subject, concluding with the assertion that the efforts of Dixon and Overton (*E. S. R.*, 21, p. 318; 25, p. 220) to refer the death of the leaves after partial death of the stem to poisoning or to plasmolysis are not conclusive; also that the same may be said in regard to Overton's defense of the view that sufficient water may be carried past killed portions of the stem for the nourishment of the leaves.

Studies on regenerative processes in plants, B. KÄBUS (*Beitr. Biol. Pflanz.*, 11 (1912), No. 1, pp. 1–52, figs. 23).—Investigations were made on both the underground and aerial parts of a considerable number and variety of plants regarding their modes and rates of forming new tissue when wounded, as for example in grafting, the conditions under which it occurs, and the factors favoring or hindering its occurrence.

It was found that cork formation in case of wounded potato tubers follows access of air. Sugar formed at the cut surface in the presence of air was partly withdrawn and partly utilized in the formation of wound periderm. The cut cells turned brown on contact with air. The presence of eyes is not necessary to the growing together at the cut surfaces by two tubers, but it does hasten such union. Lower temperatures may prevent the union even of tubers provided with eyes. The vascular bundles seemed to play an important part in this process.

In subterranean parts of *Dahlia variabilis*, *Sauromatum guttatum*, and *Bous-singaultia baselloides* the presence of buds was not necessary to union, but it

was essential to that of aerial portions. In these also the young growing leaves could be grafted at their growing points. The first impulse to union was found to proceed from the stalk. Monocotyledons, it was found, could be grafted in regions where cells were still capable of division.

**Heat evolution by wounded plants**, H. TIESSEN (*Beitr. Biol. Pflanz.*, 11 (1912), No. 1, pp. 53-106, pls. 2, figs. 13).—The author studied the thermal effects following the wounding of potatoes, apples, radishes, carrots, and beets.

The wounding of tissues was followed by a rise of temperature which was greatest immediately at the wounded surface. The duration of this phenomenon varied between one-half and 3 days, the elevation of temperature ranging from 0.02 to 0.08° C. with an average of about 0.04°. The maximum elevation was reached on an average in 1 hour after wounding (in extreme cases from 15 minutes to 3 hours thereafter). The details of the phenomenon were found to vary for different classes of objects studied. Objects of the same kind under conditions exactly alike exhibited individual differences as regards heat response to wounding, while halves of the same object invariably showed no differences in this respect.

**Arsenic in some parasitic or parasitized plants**, F. JADIN and A. ASTRUC (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 4, pp. 291-293).—The results of the authors' analyses, carried out with 19 parasitic and 12 host plants, are considered to justify the following conclusions:

Parasitic plants on hosts growing directly in the soil contain normally a certain quantity of arsenic. Mistletoe, though found growing in unlike regions and on very different kinds of trees, uniformly contains practically the same proportion of arsenic, although the host plants may show an appreciable difference in this respect. It has not been found possible to establish a proportion between the arsenic content of the parasite and that of its host.

**Some quantitative determinations of manganese in plants**, F. JADIN and A. ASTRUC (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 6, pp. 406-408).—Continuing the above studies, the authors present their findings as to manganese.

They find this constantly present in plants, thus explaining wholly or in part the origin of this element in the animal organism. The chlorophyll-bearing parts of the plant appear to have more manganese than the underground portions. In case of a plant rich in chlorophyll, such as mistletoe, manganese was found to vary greatly from causes not yet ascertained.

**Variations in the proportion of nicotine in different organs of the tobacco plant during its vegetative period**, E. CHUARD and R. MELLET (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 4, pp. 293-295).—Analyses were made of leaves, stems, roots, suckers, and buds of tobacco plants taken on July 14, August 9, September 18, and November 4.

It was found that the nicotine content in the leaves, stems, and roots increased rapidly during the first period; that in leaves increased little during the second and not at all during the third period; while in stems and roots it declined steadily after August 9. In the shoots it reached a maximum September 18. In the tips it did not increase after July 14.

**The influence of tobacco smoke on plants**, H. MOLISCH (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl.*, 120 (1911), I, No. 7, pp. 813-838, figs. 4).—Continuing work previously noted (E. S. R., 27, p. 254), the author reports more fully on the effects of tobacco smoke on plants, as follows:

Micro-organisms were quickly injured or killed by tobacco smoke. Plants showed great differences in their mode of reaction thereto. *Tradescantia guianensis*, *Selaginella martensii*, *Tolmiea menziesii*, *Eupatorium adenophorum*, species of *Echeveria*, etc., suffered little injury or check from tobacco fumes of

moderate density. On the other hand, some showed themselves very sensitive either (1) by chemotactic movements, as *Bahmeria utilis*, *B. polystachya*, *Impatiens parviflora*, and *Parietaria officinalis*; (2) by anomalous development of lenticels, as *Goldfussia glomerata*, *Salix rubra*, and *Sambucus nigra*; (3) by fall of leaves, as in case of *Mimosa pudica* and others; or (4) by limitation of anthocyanin-formation in *Strobilanthes dyerianus*.

A case of chronic poisoning of fruit trees by factory smoke, R. NASINI, G. CUBONI, and O. MATTIROLI (*Perizia Giudiziaria*, Torino, 1911, pp. 82+3; rev. in *Internat. Inst. Agr.* [Rome], *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 4, pp. 1045-1049).—This is a study of the cumulative effects on the sweet orange (*Citrus sinensis*) of poisoning by sulphur dioxide in factory smoke. Details of the injuries are given, also recommendations for the protection of the trees.

### FIELD CROPS.

The Woburn field experiments, 1910, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 71 (1910), pp. 322-343).—This continues work previously noted (E. S. R., 23, p. 632). The season of 1910 was unfavorable, the land wet and cold, and germination much delayed.

On the plats on which wheat and barley have been grown continuously the thirty-fourth year's yields on the check plat averaged 14.1 and 13.5 bu. per acre, respectively, as compared with 25.1 and 11.7 bu. after rape dust equivalent to 25 lbs. of ammonia; 24.1 and 20.3 bu. after mineral manures and sulphate of ammonia equivalent to 25 lbs. of ammonia on the plats to which 1 ton of lime had been added in 1905; and 27.8 and 31.5 bu. after mineral fertilizers and nitrate of soda equivalent to 50 lbs. of ammonia.

In rotation tests, the plat of swedes fed off by sheep that received decorticated cotton cake in addition produced a little more barley than the check plats, but the plat on which sheep were fed corn meal produced the lowest barley yield in this portion of the test. When cattle were similarly fed, there was little difference in yield on the cotton cake and corn meal plats, but each produced 4 or 5 bu. more than the check plats. In another rotation, the wheat yield following mustard during the fourth year after the cotton cake and corn meal had been fed on the land indicated that the residual effects of the manure had been practically exhausted by this time. With a third rotation, using sheep the yield of swedes after wheat was somewhat lower on the corn and cotton cake plats than on the check plats, but with cattle the swede yield was about 2½ tons per acre greater on the cotton cake plat than on the check plats, while the corn-meal manure apparently gave no profit. In a fourth rotation, mustard after barley gave a lower average yield on the corn meal and cotton cake plats than on the check plats.

Mustard and rape plowed under as green manures were followed by much higher wheat yields than were vetches and each of the three was followed by a considerably higher yield when plowed under with lime than with mineral manures. This difference in favor of lime had not been noted in the earlier years of this test and may be due to the depletion of the lime content of the soil. The indication of the superiority of mustard as green manure, however, is in harmony with the results of earlier experiments.

In 1910, as in each of the 4 previous years of the test, a Canadian alfalfa seed gave markedly higher yields than did two other varieties designated as Provence and American.

An application of 2 tons of lime was followed by a yield of 38.1 bu. of wheat as compared with 37 bu. on the no-lime plat, and 42.1 bu. on the plat which received 10 cwt. of ground lime in 1907 and the same amount in 1909.

In a test of nitrogen sources for oats, each applied in quantities supplying the amount of nitrogen contained in 1 cwt. of sulphate of ammonia, a wheat yield of 1,916 lbs. was obtained after the use of calcium cyanamid; 1,812 lbs. after calcium nitrate; 1,779 lbs. after nitrate of soda; and 1,771 lbs. after sulphate of ammonia, as compared with 1,572 lbs. on the check plat.

In another test of nitrogen sources, each applied in amounts supplying the same amount of nitrogen as that contained in 1 cwt. sulphate of ammonia, and each accompanied by a so-called standard dressing consisting of 12 tons of dung, 3 cwt. of superphosphate, 1 cwt. sulphate of potash, and 2 cwt. salt, a yield of 29 tons 3 $\frac{3}{4}$  cwt. of mangels was secured after the use of sulphate of ammonia, 34 tons, 15 cwt. after nitrate of soda, 36 tons 16 $\frac{3}{8}$  cwt. after calcium nitrate, 35 tons 15 $\frac{5}{8}$  cwt. after calcium cyanamid, and 33 tons after soot. From this test the author concludes that calcium cyanamid and calcium nitrate appear to equal or excel nitrate of soda as fertilizers for mangels. The planting of mangels on plats to which these nitrogen sources had been applied the previous year indicated "that the residue left over for a second crop was in no instance of material value."

In a test of 10 wheat varieties, the Dutch variety *Wilhelmina* produced a much higher yield than any other tested but was poor in strength, while *Red Admiral* produced a much higher yield than any other English or French variety tested. Two Cambridge varieties designated as No. 1 and No. 2 excelled the others in quality but No. 2 was the lowest yielding variety tested.

In a meadow fertilizer test an application of 10 cwt. of basic slag and 1 cwt. of sulphate of potash per acre was followed by a yield of 1 ton, 15 $\frac{3}{4}$  cwt. of hay per acre as compared with 1 ton, 18 $\frac{1}{4}$  cwt. after 12 tons of farmyard manure and smaller yields after other mixtures of superphosphate, basic slag, nitrate of potash, and sulphate of potash in various mixtures. The hay containing the highest percentage of legumes and the lowest percentage of grasses followed an application of superphosphate and sulphate of potash, while the lowest percentage of legumes and the highest percentage of grasses was obtained from the no-manure plat.

**The Woburn field experiments, 1911, J. A. VOELCKER** (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 387-403).—This continues the work noted above. The prolonged drought of 1911 was especially severe on the grain crops on this light sandy soil.

On the plats on which wheat and barley have been grown continuously, the thirty-fifth year's yields of these 2 crops on the check plats averaged 8.2 and 2.6 bu. per acre, respectively, as compared with 20.2 and 26.7 bu. after farmyard manure equivalent to 100 lbs. of ammonia; 21.8 and 3.8 bu. after nitrate of soda equivalent to 50 lbs. of ammonia; 21.6 and 1.7 bu. after half this amount of nitrate of soda; and 20.2 and 6.2 bu. after 1 cwt. of sulphate of potash and nitrate of soda equivalent to 25 lbs. of ammonia. On the wheat plats an application of sulphate of ammonia equivalent to 25 lbs. of ammonia was followed by a yield of 1.4 bu. as compared with 19.1 bu. after the same amount of sulphate of ammonia supplemented by 5 cwt. of lime in January 1905, repeated in 1909 and 1910. These same fertilizers, and superphosphate and rape dust singly and in various mixtures and amounts were also applied to 14 other plats.

A higher yield of grain and straw was obtained from a wheat plat fertilized with the manure from corn-fed cattle than in case of the check plats or a plat fertilized with the manure from cattle fed on decorticated cotton cake. On land on which the previous year's swede crop had been consumed by sheep which were fed corn on the plats, the wheat yield was 2 cwt. and the straw yield over 3 $\frac{1}{4}$  cwt. greater than on the plat where the swede crop had been

consumed by cake-fed sheep. The cake-fed sheep received chaff and equal parts of linseed and undecorticated cotton cake, while the grain-fed sheep received chaff and equal parts of barley and oats in addition to the swedes.

In a test of nitrogenous top dressings supplying the amount of nitrogen contained in 1 cwt. of sulphate of ammonia, a wheat yield of 1,240 lbs. followed nitrate of soda as compared with 1,026 lbs. after nitrate of lime, 1,016 lbs. on the check plot, 959 lbs. after sulphate of ammonia, 1,061 lbs. after calcium cyanamid, 1,174 lbs. after a mixture of equal parts of nitrate of lime and cyanamid, and 1,078 lbs. after a mixture of one part of nitrate of lime and two parts of cyanamid. The author regards the mixing of these two materials as distinctly satisfactory.

In a test of alfalfa varieties designated as American (Arizona), North American, Canadian, Turkestan, Provence, Russian (Europe), and Russian (Asia). "the two that stood out undoubtedly the best were the two American varieties."

The cost per acre of hoeing, thinning, and harvesting sugar beets planted 12, 15, and 18 in. apart was 86s. 6d., 70s. 6d., and 58s., respectively, as compared with 24s. 6d. in case of mangels planted 24 in. apart. The yields in the same order were 21 tons 1 cwt., 22 tons 13 cwt., 23 tons 15 cwt., and 44 tons 4 cwt.

Although the conclusions are deemed only tentative, it appeared that Buxton lime and chalk lime excelled lias, oolite, and magnesian limes for grass.

Report of Hedemarken County Experiment Station, 1911. W. CHRISTIE (*Ber. Hedemarkens Amts Forsöksstat. Virks.*, 7 (1911), pp. 56, pls. 2, figs. 2).—Tests of potato varieties, planting potatoes of different degrees of maturity, fall growth of potatoes, and changes occurring after harvest, dates of sowing winter rye, and the use of Thomas phosphate, nitrate of soda, and kainit as top-dressing for meadows are included in this report. The work on meadows and winter rye has extended over a period of years.

[Field crops at the Roseworthy Agricultural College], A. J. PERKINS and W. J. SPAFFORD (*Jour. Dept. Agr. So. Aust.*, 14 (1911), Nos. 10, pp. 959-967; 11, pp. 1030-1037; 12, pp. 1141-1154; 15 (1911), Nos. 1, pp. 10-25; 2, pp. 112-119).—This is the fourth report (E. S. R., 23, p. 535). Meteorological data and a general discussion of 6 years' results are followed by a statement of the results obtained in 1909-10 and 1910-11.

Rotation tests were conducted to determine whether or not local farming was possible except under the bare fallowing system now practiced. When wheat was grown continuously the yield fell from 29 bu. 19 lbs. per acre the first year to 9 bu. 15 lbs. the second year, and 3 bu. 53 lbs. the third year. In the second and third years these yields were 11 and 12 bu., respectively, below the averages of those secured after bare fallow. The hay yields were about a ton below the averages on the bare fallow plats during each of the 2 years. In a 2 years' test comparing bare fallow with (1) a turnip, barley, pea, wheat, and (2) a kale, oat, vetch, wheat rotation, the advantage in grain yield on the bare fallow was more than sufficient to pay the rental costs of idle land. During other years this difference was insufficient, and in one case the difference was nearly 3 bu. in favor of wheat grown in rotation. In hay yields the wheat grown in rotation averaged much better than that grown after bare fallow. In another rotation the returns of wheat after sorghum did not approach those secured from wheat after bare fallow. The authors conclude that under the conditions during these tests a year of bare fallow is not essential in growing wheat for either hay or grain.

In the turnip, barley, pea, wheat, rotation during 4 years, the turnips maintained the equivalent of 3.16 sheep per acre for an entire year. Similarly an

acre of barley maintained 0.94 sheep per acre per year, peas, 2.26, and wheat 0.39. In the kale, oat, vetch, wheat rotation the figures were 2.41, 0.59, 2.69 and 0.52 sheep per acre per year, respectively. The total gross returns for the two 4-year rotations were £12 4s. 1d. and £12 13s. 5d., respectively, as compared with £10 15s. after bare fallow. The increased gross return was not sufficient to cover the additional outlay involved in raising the subsidiary crops.

Three years' work indicated that in point of cereal returns a bare-fallow, wheat rotation had every advantage over a bare fallow, wheat, pasture rotation, although the net returns from the longer rotation "are likely to be quite as good if not better."

Four years' tests indicated that the average sheep-carrying capacity of pasture plats after wheat, treated with  $\frac{1}{2}$  cwt. of superphosphate, was 2.66 sheep per acre per year, as compared with 3.01, 3.09, and 3.26 head, respectively, in case of plats that received 1, 2, and 3 cwt. of superphosphate per acre. These heavier applications apparently gave a carrying capacity about 4 or 5 times as great as that "of similar land worked on ordinary station lines." In case of wheat, the heavier applications of superphosphate did not produce profitable increases in yield.

On unfertilized plats the period between germination of wheat and full bloom averaged 135 days and that between germination and ripening 180 days, as compared with 130 and 178 days on the superphosphate plats, and 126 and 173 days on the nitrate of soda plats. Although nitrate of soda apparently increased the grain and hay yields, the increases were insufficient to pay the cost of the fertilizer.

In a 5-year test applications of 2 cwt. of superphosphate either with or without  $\frac{1}{4}$  cwt. of nitrate of soda to wheat were followed by somewhat greater grain yields than were 2 or 3 cwt. of basic slag or 14 tons of farmyard manure per acre. In a 1-year test of fertilizers after bare fallow a higher wheat yield followed an application of 2 cwt. of superphosphate and  $\frac{1}{2}$  cwt. of sulphate of potash than was secured on any of 14 other plats in the test, which received applications of superphosphate with or without sulphate of potash, sulphate of ammonia, nitrate of soda, or muriate of potash in various mixtures and amounts. Eleven of these plats had been seeded continuously to wheat and decreased in average yield from 26 bu. 10 lbs. in 1905 to 5 bu. 23 lbs. per acre in 1907. In 1908 they were bare fallowed and in 1909 averaged 35 bu. and 34 lbs. of grain per acre.

[Small grain experiments at the Roseworthy Agricultural College], A. J. PERKINS (*Jour. Dept. Agr. So. Aust., 15 (1912), Nos. 7, pp. 705-713; 8, pp. 792-800*).—These pages state the results of variety tests of oats, wheat, and barley on six 1-acre plats plowed from 2 to 12 in. The highest wheat yield was obtained from the plat plowed 8 in. deep.

[Depth of sowing tests], A. J. PERKINS and W. J. SPAFFORD (*Jour. Dept. Agr. So. Aust., 15 (1911), Nos. 3, pp. 208-216; 4, pp. 353-362; 5, pp. 479-498; 15 (1912), No. 6, pp. 608-623, fig. 1*).—Tables state in detail the germination secured by sowing at 12 different depths ranging from  $\frac{1}{2}$  in. to 6 in. during the 3-year period, 1906-1909. The seeds were generally planted on duplicate plats in sandy soil and in a heavy clay loam, and not all were sown throughout the 3-year period.

Wheat germinated most freely in sandy soil when sown from  $\frac{1}{2}$  in. to 1 in. deep, and fairly satisfactorily up to 4 in. but beyond that depth germination was irregular, although 50 per cent of the plants finally came up even after sowings 6 in. deep. In heavy clay loam, germination was best at a depth of 1 in. but continued fairly satisfactory to a depth of 2 $\frac{1}{2}$  in., while below 4 $\frac{1}{2}$  in. more than 50 per cent was lost.

In light sandy soil from 1½ to 2½ in. appeared to be the best depth for sowing barley, although satisfactory results were obtained at depths of 4 in. beyond which a greater proportion of the plants died back. In heavy clay loam from ½ to 2½ in. appeared to be the normal depth of planting, and the highest yields of grain were secured from sowings between 1 and 2 in. deep.

Oats in light sandy soil germinated best at depths between 1½ and 2½ in., but might be planted 4 in. deep without much danger of serious loss from faulty germination. About three-fifths of the seed sown germinated successfully at a depth of 6 in. The germination of oats sown from 1½ to 2½ in. deep took place between the tenth and thirtieth days after sowing, as compared with the ninth and eighteenth days for barley, and the tenth and twenty-first days for wheat sown at similar depths. In heavy clay loam from 1½ to 2 in. appeared to be the best depth of sowing for oats, but fully three-fourths of the seed sown 5½ in. deep germinated successfully. The proportion of plants dying back increased steadily at depths greater than 4 in.

One year's tests indicate that on sandy soil field beans and peas will give a germination of from 90 to 100 per cent at all depths between ½ in. and 6 in.

From 2 years' work it was not possible to state in figures a depth of planting corn that would be applicable to all cases. Shallow planting appeared likely to result in late and irregular germination depending almost entirely upon the rains following planting.

For sorghum about 1 in. appeared to be the best depth of sowing if sufficient moisture in the surface soil layer could be relied upon. Under ordinary circumstances, however, sowing from 1 to 2 in. deep in heavy soils or from 2 to 2½ in. deep in light soils, and in case of late seeding even deeper sowings, are recommended. Millet should not be sown more than 1 in. deep on heavy land or 1½ in. on light soil.

[Fertilizer tests on meadows], G. BREDEMANN (*Fühling's Landw. Ztg.*, 61 (1912), Nos. 5, pp. 166-191; 6, pp. 210-229).—A brief summary of earlier work is followed by statements of the results of fertilizer tests on meadows extending over a considerable period of years at each of a number of German experiment stations. The fertilizer mixtures applied were (1) Thomas meal and kainit; (2) Thomas meal, kainit, and every fourth year quicklime, and (3) Thomas meal, kainit, and every fourth year a double application of quicklime. Mechanical and chemical analyses of the soils of each of the stations are given.

Cooperative experiments with alfalfa, M. F. MILLER and C. B. HUTCHISON (*Missouri Sta. Bul.* 106, pp. 23-56, figs. 8).—The experiments here reported, begun in 1907, were increased in number from year to year and finally furnished data from 74 of the 114 counties of the State. Each cooperator was instructed to devote 1 acre to the test and to divide this into 4 equal plats. The first plat was to receive 12 tons of manure per acre, the second 3,000 lbs. of lime, the third 300 lbs. of steamed bone meal, and the fourth was to receive no soil treatment. Two-thirds of each plat was to be inoculated and one-half of the inoculated portion given cultivation with a disk or spring-tooth harrow. The results of the individual experiments as well as summaries based on the soil types and the soil treatment are given in tables and discussed.

The data secured in this cooperative work indicated that alfalfa does not have as wide adaptations as most forage crops grown in the State. The most important factors in the success of the crop were drainage, the character of the subsoil, the fertility, and the quantity of lime carbonate present. The well-drained silt and sandy loam bottom lands with porous subsoils proved to be the best alfalfa lands of the State. On upland soils the best results were secured on the fertile, rolling prairies of the north and west central part, the

better timbered lands of north Missouri, and the more fertile valley lands of the Ozark region. The number of failures was largest on the level prairie lands.

The application of manure was found beneficial and often necessary in securing a satisfactory stand on most upland soils. The use of bone meal on the upland soils, which are mostly lacking in available phosphates, appeared profitable. Most of the soils of the State adapted to alfalfa growing are well supplied with lime carbonate and hence lime did not usually give profitable returns. In most cases inoculation of the soil was found beneficial or necessary, and cultivation of the crop with the disk or spring-tooth harrow was found effective in preventing the growth of grasses during late summer.

**Alfalfa seed production**, R. W. THATCHER (*Washington Sta. Popular Bul.* 42, pp. 4).—Cooperative work of the station and this Department in the production of alfalfa seed is briefly reported.

Thinning experiments carried on in this connection showed conclusively that a much better yield of seed may be obtained from a thin than from a dense stand of alfalfa, but the work is to be continued. From the results of some of the experiments, as well as observations made in another connection, it appears probable that with proper thinning large crops of seed may be secured.

**The development of the grain of barley**, WINIFRED E. BRENCILEY (*Ann. Bot.* [London], 26 (1912), No. 103, pp. 903-928, figs. 22).—Pursuant to previous studies on the development of the grain in wheat (E. S. R., 24, p. 37), the author investigated samples of barley from plants so selected as to show the results obtained (1) from a nitrogenous general manuring, (2) a rotation without any addition of manure, and (3) phosphoric acid starvation in the presence of a sufficiency of nitrogen and of potash and other alkalis. The results may be summarized as follows:

The weight of the plant as a whole, also of the nitrogen, phosphoric acid, and ash, increase until desiccation begins about 3 weeks before harvest. After this the ash decreases somewhat, while the nitrogen and phosphoric acid continue fairly constant. The phosphoric acid-starved plot, in case of barley, showed somewhat abnormal results, especially in the analysis of the straw. During the longer desiccation period of barley certain maturation changes are evident which are hardly noticeable in wheat, which is cut earlier in its development. The infiltration of starch progresses from the chalazal end toward the embryo. As the barley grain develops, nuclear changes appear, thought to be due to pressure from increase of starch. The nuclei lose their nucleoli and become deformed progressively from both ends of the grain toward the middle, the last cells involved being those of the subaleuronic layer of the endosperm.

**[Clover tests in Denmark]**, E. LINDHARD (*Tidsskr. Landbr. Plantearl.* 19 (1912), No. 1, pp. 1-3).—The experiments reported include variety and rate of seeding tests conducted at Danish experiment stations with alsike clover, white clover, yellow trefoil, and kidney vetch. Seed grown in various counties was also tested.

**Increasing the yield of a strain of Reid yellow dent**, J. R. HALL (*Col. Farmer* [Univ. Missouri], 9 (1912), No. 4, pp. 7, 8, fig. 1).—The author summarizes some results of Williams and Welton already noted (E. S. R., 23, p. 37).

From his own experiments he concludes that it is impossible to detect the highest yielding ears of seed corn by inspection, but he states some indications of high yielding power. In a 2 years' test the ears over 9 in. averaged 3.68 bu. higher yields than those under 9 in. in length. Cylindrical ears yielded 1.5 bu. per acre more than tapering ears, moderately smooth ears yielded 4.87 bu.

more than moderately rough ears, and heavy ears showed an average advantage of 3.9 bu.

**Mendelian inheritance in cotton hybrids**, C. A. McLENDON (*Georgia Sta. Bul.* 99, pp. 139-228, figs. 27).—This bulletin is a report of progress on experiments in cotton breeding conducted for 3 years and including only the second generation of the first crosses made.

The varieties and types entering into this work were Willet Redleaf, Cook Bigboll, Hastings Bigboll, Pride of Georgia, Toole, Sistrunk, Russell Bigboll, Cleveland Bigboll, Ratteree Favorite, Blue Ribbon, and Sea Island. From a trial plat planted with commercial seed of the different varieties the parent stock was selected on the basis of superiority and general appearance. Several series of crosses were made in each instance and when the progeny of the parent plants and the  $F_1$  generation of the crosses were grown, all of the series except those from parents showing their purity were eliminated. Six series of crosses were made the first year and 3 additional series the second between varieties of tested purity. The methods employed are described in detail, particular attention being given to crossing and selfing. The inheritance of characters is discussed and tables are given showing the dominant and recessive characters, together with the ratio of segregation. A list of 37 allelomorphous pairs of unit characters in the cotton plant is presented and a bibliography of 28 references on Mendelian inheritance and natural crossing in cotton is appended.

The results of 2 experiments conducted on a limited scale showed that natural crossing occurs, but that most if not all insects causing it may be excluded from the plants by means of netting.

It is concluded from the results secured that the heritable characters in the crosses studied seem to obey Mendel's laws of dominance, segregation, and recombination. Dominance was found incomplete for several characters which rendered the heterozygote intermediate and gave a greater range of visible variation in crosses having two or more characters correlated. Segregation into the 1:2:1, 3:1, 9:3:3:1, and 15:1 ratios was indicated in these experiments, but the exact theoretical proportions occurred in only a few instances, this being considered due either to the small number of individuals or the heterozygous condition of the parent stock. Intensification of the characters in crosses between Sea Island and Upland varieties was very common in the  $F_1$  generation, but in the succeeding generations it gradually diminished. Fluctuation was infrequent in pure strains but very common in lint characters, even in apparently homozygous individuals. Variations of economic importance were of frequent occurrence, but they were usually if not always the result of crossing.

**Fertilizer tests of oats**, F. GAUL (*Illus. Landw. Ztg.*, 32 (1912), No. 10, pp. 75, 76).—Tables report the results of a number of years' tests of ammonium sulphate, nitrate of soda, nitrate of lime, Thomas meal, and kainit singly or in various mixtures as fertilizers for oats in Thuringia.

From the data presented the author concludes that on light dry soil, ammonium sulphate harrowed in at the time of planting proved the best nitrogen fertilizer for oats. Thomas meal and kainit gave no profits when applied to oats after winter grain, but may be used when oats are a nurse crop for clover. Kainit and a 40 per cent potash salt may be used on a heavy soil that tends to the formation of a crust.

**The influence of different amounts of water on the yield and quality of sugar beets**, A. HERKE (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 41 (1912), No. 1, pp. 1-7).—Analyses of beets grown in concrete and other pots, to which water was applied at 3 different rates each year, are reported in tabular form. Parallel series of experiments were conducted on 3 different soils.

Other tables report the amount of water used per kilogram of plant substance produced by the plants.

The total nitrogen content in the roots decreased as the amount of water applied increased, but probably no less nitrogen was absorbed by the large heavily watered beets, as the nitrogen rose to the foliage in this case. The decrease in the total nitrogen content was even more rapid than the increase in the amount of water applied, and the quality of the beets was improved. This is in harmony with the common observation that during dry seasons the injurious nitrogen content is high.

The composition of sugar beets of different sizes, A. HERKE (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 41 (1912), No. 1, pp. 8-12).—Each of a number of lots of beets was sorted, on the basis of weight, into 3 groups. Tables show the chemical composition of the beets in each group.

Soaking beet seed, G. KÖCK (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 41 (1912), No. 1, pp. 13-15).—Soaking beet seed 20 hours in pure water gave a quicker, more even germination, healthier and more vigorous plants, and heavier beets. The results of treating with 0.5 per cent carbolic acid are also briefly reported.

The germination of hulled timothy seed, B. KAJAMUS (*Fühling's Landw. Ztg.*, 60 (1911), No. 12, pp. 431-434).—Tests of 19 samples grown during the year preceding the test showed an average germinating power of 93 per cent for the seed without hulls, and 97.5 per cent for that with hulls. In case of a poorly stored sample the tests were 61.3 and 64.3 per cent, respectively. This seed was probably immature. In another group the author includes 6 samples in which the seed with and without hulls showed average germination tests of 79.5 and 42.9 per cent, respectively. He concludes that storage affects more quickly the seeds which have lost their hulls, and that they are more subject to mold. Their metabolic processes are hastened and the germ dies more quickly.

Tobacco: Breeding cigar filler in Ohio, A. D. SELBY and T. HOUSER (*Ohio Sta. Bul.* 239, pp. 361-479, figs. 30).—This bulletin, continuing previous work (E. S. R., 27, p. 237), states the conditions surrounding tobacco improvement in the Ohio tobacco filler district, and records the results in producing new types by selection and hybridization at the Germantown test farm in cooperation with the Bureau of Plant Industry of this Department. The theory and practice of hybridization and tobacco breeding are discussed in detail and the more important hybrids originated in this work are described.

The selection of individual seed plants of Zimmer Spanish resulted in no progress toward a better quality or a higher yield, and indicated that improvement was possible only by the method of crossing followed by selection. In 1906, plants from seed 15 years old and which germinated nearly as well as new seed did not differ in character or yielding capacity from other Zimmer Spanish tobacco grown. In 1910, old seed claimed to have passed through but 2 generations since the original supply had been obtained from the supposed originator of the variety, produced less than the checks grown with it, and the tobacco again appeared exactly like the ordinary Zimmer Spanish of to-day. These results are believed to disprove the claim that the variety is running out.

Results obtained in 4 different years with Connecticut Havana led to the conclusion that this variety is identical with Zimmer Spanish. These results were also regarded as showing a remarkable fixity of type in which even radical changes of environment do not produce inheritable variation.

In 1906, Ohio Seedleaf and Pennsylvania Seedleaf in a comparative test yielded 44.6 and 40.6 per cent more respectively than Zimmer Spanish. For the 4 years 1907-1910, selections of Pennsylvania Seedleaf, numbered 9 and 12, pro-

duced an average gain per acre over Zimmer Spanish of 428 lbs., or 43.9 per cent, and 482 lbs., or 52.1 per cent, respectively.

Experiments with the Cuban variety indicated that considerable improvement in yield and in the reduction of suckers is possible through selection. By this means, the yield was increased from slightly over one-half to more than three-fourths of the yield of Zimmer Spanish. As the yielding capacity of the variety is so low, no practical results were obtained. Under the conditions existing in the Miami Valley district, this variety undergoes a marked breaking up in type, but the range in variation was not found so great as in hybrids between radically different varieties.

Hybridization work was begun at Germantown in 1903 by making 26 distinct crosses between Connecticut Seedleaf and Cuban varieties. In 1904, crosses were made between these first hybrids and Ohio Seedleaf and Zimmer Spanish, together with one each between Zimmer Spanish and Ohio Seedleaf and Zimmer Spanish and Cuban. The next year a large number of crosses were made between Cuban, Zimmer Spanish, Ohio Seedleaf, and several hybrids already made in divers combinations. Since that time, new hybrids have been made each year, among them a number whose parents were both of Seedleaf type.

The hybrids are arranged in 4 groups of which the first includes the Havana or Spanish types, more or less closely approaching Zimmer Spanish, the second contains the Seedleaf class, the third those intermediate between Seedleaf and Spanish, and the fourth the Cuban and Connecticut Seedleaf hybrids. Of the 26 hybrids between Cuban and Connecticut Seedleaf made in 1903, only 5 were retained as worthy of propagation. The variation in this lot of hybrids was extreme, and in the second generation it was so great that no 2 plants of sufficient individual merit to warrant propagation bore any considerable resemblance to each other.

The individual annual records of the important members of each group of hybrids are summarized in tables. A comparison of yields of 24 hybrids and 8 varieties presented a general increase in the relative yields of the hybrids during the 3 years 1908-1910. The average increase per acre over Zimmer Spanish for all hybrids in 1908 was 189 lbs., in 1909 227 lbs., and in 1910 405 lbs.

Experiments to determine the possibility of growing tobacco crops as first-generation hybrids were carried on during several seasons. Zimmer Spanish was selected for determining the effects of cross-fertilization within the limits of a fixed variety. The average of all results gave a gain of only about 25 lbs. per acre in favor of cross-fertilization. The lack of variation in Zimmer Spanish, or its fixity of type, is given as a possible explanation of this result. In 1907, pairs of plants of distinct varieties were selected and 2 lots of seed from each plant, one arising from self and the other from cross-fertilization, were secured. The results of this seed from 8 plantings for each pair of parent plants showed that in all cases the hybrids exceeded in yield not only the average of their parents but also their more productive parents. The minimum increase per acre was 67 lbs., while the maximum was 285 lbs., and the average 165 lbs. In 1909, 39 new hybrids were tested in a similar way with their parent plants. These hybrids, in most cases produced considerably more than the parental average, but a number of them failed to reach the yield made by the more productive parent. This year the hybrid yields ranged from a minimum of a decrease per acre of 160 lbs. to a maximum of an increase of 492 lbs., the average of the hybrids being about 185 lbs. greater per acre than that of their parent plants. In discussing the relation of parental yields to that of hybrids, the authors state that in many instances they have been able to produce in the third and later generations yields much in excess of the yield of the first gen-

eration. They report their failure to produce a first-generation yield equal to the combined yield of both parents, which was accomplished several times in later generations. In reviewing the possibility of producing first-generation hybrids on a commercial scale, it is estimated that the extra cost should not exceed 50 cts. per acre.

A study of certain strains of some of the hybrid varieties indicated the possibility of breeding for special adaptations. Among the hybrids produced some exhibited great drought resistance and others a much greater ability to make profitable use of the less available or more slowly available forms of plant food such as barnyard manure or other forms of organic matter and certain ingredients often found in commercial fertilizers.

Cooperative tests by farmers were conducted in 1909, 1910, and 1911. In 1910, Hybrid S1 was given out for the first time and immediately found favor with many growers on account of its erect habit of growth, hardiness, and great ability to withstand windstorms. In yield it made from 13 to 46 per cent more than Zimmer Spanish under the same conditions. The cured tobacco of this hybrid is almost undistinguishable from that of Zimmer Spanish, and its smoking quality has proved equal to or better than that of Zimmer Spanish. It is stated that the total number of cooperative growers for 1912 is about 100 and that the total acreage of hybrids to be grown in these tests will amount to over 250 acres planted largely to Hybrids S1, 224, and 199. Hybrids S1 and 224 of the Spanish types, Hybrid 199, a Seedleaf type, and Hybrid 110, which is intermediate in character, are especially recommended for trial.

Smoking tests of Ohio filler tobacco are reported and discussed. It was found that there was no apparent connection between nicotine content and smoking quality.

The influence of superphosphates on the germination of wheat, A. J. EWART (*Jour. Dept. Agr. Victoria, 10 (1912), No. 4, pp. 256-258*).—The author notes that it has frequently been stated that the germination of wheat may be easily affected if it lies long in contact with superphosphate of lime in a dry soil. The injury is pronounced only when the seed germinates and the soil subsequently dries.

Seeds stored dry with an equal quantity of dry superphosphate gave germination tests averaging 91.25 per cent at the end of 3 weeks, and 87 per cent at the end of 6 weeks, as compared with 91 per cent at the end of 3 weeks in case of the seed stored without superphosphate. The author concludes that little or no injurious effect is exercised under these conditions in a moderate length of time.

In a field test, superphosphate was applied with the grain 1 in. deep, 1 in. below the seed and 3 in. below the seed. The deeper plantings were invariably followed by considerably greater yields.

Wheat experiments, season 1911, H. ROSS ET AL. (*Agr. Gaz. N. S. Wales, 23 (1912), No. 4, pp. 277-293*).—These pages report the results of farmers' variety tests of wheat in 4 different districts, fertilizer and smut prevention tests, and trials of mixed sowings of wheat and oats for hay.

Seed laboratory report for 1910 and 1911, W. L. OSWALD (*Minnesota Sta. Bul. 127, pp. 129-163, pls. 2, figs. 12*).—Following introductory remarks on the objects of the Minnesota seed laboratory by E. M. Freeman, the bulletin describes methods of seed testing employed, reports the source of the seed samples received, presents results of purity and germination tests, and describes a weed-seed ease for the identification of weed seeds.

During the 2 years, 2,275 tests for purity were made. It was found in this work that out of a total of 59 different weed seeds found, 36 occurred in the different samples of medium red clover. Only 4 different varieties were found

in rye. The seeds of lamb's quarters and pepper grass appeared in 14 of the 16 crop seeds examined, while dodder seed appeared only in alfalfa and red clover. Green foxtail and lamb's quarters were the most common weed seeds found. Of the millet samples examined, 96.2 per cent contained green foxtail seed. A large number of all samples tested were below the standard of purity.

On the average, all germination tests gave a higher average in 1911 than in 1910. Brome grass had a very low percentage of germination. The average germination of hard seeds in alfalfa was 16.125 per cent, in medium red clover 10.45 per cent, in mammoth clover 6.5 per cent, in white clover 19.41 per cent, and in alsike clover 12.55 per cent. Some tests of alfalfa at the laboratory showed from 50 to 75 per cent of hard seeds.

The approximate number of various crop and weed seeds per pound was determined and is reported in tables.

[Seed analyses and experiment station results], F. G. STEBLER (*Landw. Jahrb. Schweiz*, 25 (1911), No. 5, pp. 149-170).—These pages report the results of purity and germination tests of the seeds of legumes, grasses, grains, fiber crops, root crops, and forest trees at the Zurich Seed Control Station. They also give a brief report of other work under way (E. S. R., p. 239).

Period of germinability of the seed of *Cuscuta epilinum*, A. HERZOG (*Deut. Landw. Presse*, 39 (1912), No. 27, p. 321, figs. 3).—A table containing the results of annual germination tests of the seed of *C. epilinum*, conducted during the period 1897-1911, indicates that the percentage of the seed which germinated in the first 5 days of the test gradually decreased from 90 in 1897 to 4 in 1906, and that the seed appeared to be entirely dead during 1910-11.

## HORTICULTURE.

Report of the horticulturist, C. F. KINMAN (*Porto Rico Sta. Rpt. 1911*, pp. 24-27, pls. 3).—A progress report of the year's work with fruits, vegetables, and miscellaneous plants (E. S. R., 25, p. 740).

In the cooperative fertilizer experiments with citrus fruits the complete fertilizers continued to give the best results. A study of the navel oranges growing in Porto Rico indicates that there is a great variation in regard to the quality of the fruit. Material has been collected from different orchards on the island and experiments to determine the cause of variation in quality are under way. The evidence in some cases indicates that this difference is due to bud variation.

Experiments in fumigating young pineapple plants taken from fields badly infested with mealy bugs have shown that a fumigation strong enough to assure clean plants at setting without injury to the plants can be made. The fumigation, however, has only a temporary effect and the customary practices must be employed in keeping the plants free from insects after they have been set in the field.

The work with cover crops in citrus orchards was extended to pineapple and coconut plantations. Cowpeas, velvet beans, sword beans, and pigeon peas have given good results. Cowpeas were found to be inferior to the other crops for summer planting on heavy soils as they mature early and often at a time when the soil is too wet for replanting or caring for a new crop properly. The other crops mentioned continue their growth throughout the season of heavy rains and make a dense cover that keeps down all the grass and weeds and also serves to prevent soil washing. Good crops of seed were secured from cowpeas planted in the spring, although winter-grown crops of *Canavalia* and velvet beans are more prolific. *Canavalia* and velvet beans planted on low, heavy

land April 10 yielded 12½ tons and 9 tons per acre of vines, green weight, respectively, 94 days from planting.

A study of the degenerating influence of Porto Rican conditions on a number of imported vegetable varieties started 2 years ago indicates that at least the okra and beans have degenerated both in vigor of the plants and productiveness. Cultural, fertilizer, and variety tests with yautias, dasheens, and yams were continued with good results. Of the yams Potato and Guinea seem to be the most promising in Porto Rico.

A test of several varieties of strawberries imported from the United States indicates that this fruit is poorly adapted to Porto Rican conditions. Of the eucalypts which are being tested in low, heavy lands, *Eucalyptus robusta*, *E. piperita*, and *E. tereticornis* have been the only varieties to make satisfactory growth.

A study of the imported varieties of bananas in the station's plantings shows that there are many duplicates due to the common names used in the countries from which they were sent. The work with mangoes was continued along previous lines.

Report of the government horticultural experimental fields in South Holland for 1911. C. H. CLAASSEN ET AL. (*Verslag Rijkstuinbouwproefvelden Zuid-Holland, 1911, pp. 96, pls. 2*).—This is the usual report for 1911 on co-operative cultural, variety, fertilizer, and spraying experiments with fruits and vegetables conducted at different localities in South Holland (E. S. R., 25, p. 642).

Note on the dipping or warm bath method of forcing plants, S. T. PARKINSON (*Jour. Southeast. Agr. Col. Wyc, 1911, No. 20, pp. 361-366, pl. 1*).—Additional tests of the warm bath method of forcing plants (E. S. R., 25, p. 536) are reported. The results on the whole confirm those previously obtained.

The kitchen garden, L. PICHENAUD (*Le Jardin Potager. Paris, 1912, pp. 234, figs. 89*).—A practical treatise on amateur and market gardening. Part 1 deals with the general principles of gardening, garden equipment, etc.; part 2 contains detailed cultural directions for various classes and kinds of vegetables; and part 3 comprises a working calendar for the year.

The production of mushrooms in quarries by the means of a pure culture obtained by a new process, G. BOYER (*Proc. Verb. Soc. Sci. Phys. et Nat. Bordeaux, 1910-11, pp. 46-50*).—The author's method of producing pure mushroom spawn in a sterilized medium is described.

The effect of manganese on pineapple plants and the ripening of the pineapple fruit, E. V. WILCOX and W. P. KELLEY (*Hawaii Sta. Bul. 28, pp. 20, pls. 2*).—The studies reported in this bulletin were undertaken in continuation of previous investigations relative to the effect of manganese on pineapples and of the chemical composition of pineapple fruits in different stages of development (E. S. R., 25, p. 340; 27, pp. 118, 129). In addition to the chemical investigations a microscopic study was made of all the different parts of pineapples for the purpose of learning the structural changes produced by the presence of large quantities of manganese in the soil and the morphological changes which occur in the ripening of the fruit. The authors call attention to the fact that anatomical and chemical findings are in striking harmony.

The root system of pineapples was found to be very variable and particularly sensitive to adverse soil conditions. In manganiferous soils the roots are less extensive and have characteristic swollen tips. These swellings seem to mark the cessation of the lateral growth of the roots, death and decay immediately following their development. The most conspicuous effect of manganese on the plant is seen in the bleaching of the chlorophyll, which first begins to fade, the chloroplasts lose their organized structure, after which the color disappears

altogether. Calcium oxalate is much more abundant in pineapple plants growing on manganiferous soils. The ash of such plants also contains considerably more lime and less phosphorus pentoxid and magnesia than when grown on normal soils.

The stem of pineapples serves as a repository for starch and contains large amounts of this substance. The leaves, in common with other members of Bromeliaceæ, contain several rows of palisade cells which contain nothing but cell sap, and the chlorophyll is confined to the spongy parenchyma in the lower three-fifths of the leaf. The fruit contains only faint traces of starch during early growth and none when it reaches maturity. During the growth of the fruit relatively small amounts of sugars are stored in it, but there is a rapid accumulation of sugars within the short period of normal ripening. The sugars of the fruit are derived from the starch previously stored in the stalk, hence pineapples gathered green do not develop a normal sugar content in subsequent ripening.

The authors found that the pineapple is exceedingly sensitive to adverse physical and chemical conditions in the soil. They suggest that other crops less sensitive to manganese than pineapples be grown on highly manganiferous soils. Thus far the best method of handling pineapples on manganiferous soils consists in applying soluble phosphates and planting old stumps instead of suckers.

The thirty years' record of a grass orchard, C. H. HOOPER (*Jour. Bd. Agr. [London]*, 19 (1912), No. 7, pp. 541-545).—A summarized account extending over 30 years is given of a small orchard, chiefly of cherries, showing actual returns and the method of cultivation adopted during that period.

An experiment in breeding apples, U. P. HEDRICK and R. WELLINGTON (*New York State Sta. Bul.* 350, pp. 141-186, pls. 18).—An experiment in breeding apples along Mendelian lines is here reported. The material for this work was derived from 148 crosses made in 1898 and 1899. The crosses were studied from both grafts and seedlings. Various numbers of the following crosses fruited: Ben Davis×Esopus, Green Newtown, Jonathan, McIntosh, and Mother; Esopus×Ben Davis and Jonathan; McIntosh×Lawyer; and Ralls, Rome, and Sutton×Northern Spy. A tabulated description of the crosses shows the size and shape of tree, yield in 1911, and the size, shape, color, flavor, and season of fruit, together with comparative notes. The transmission of characters among the different crosses is discussed and descriptions are given of a number of promising varieties secured from the crosses and named after counties in the State.

The authors find that these crosses strikingly contradict the idea that seedling apples revert to the wild prototype. The stimulus of hybridity was very marked in the vigor of the crosses under consideration, and the behavior of some of the crosses strongly suggests that apples may be prepotent in one or more of their characters. It is concluded that although the inheritance of skin color, flesh color, size, and shape is more or less hypothetical, acidity is undoubtedly inherited as a Mendelian character.

In regard to color of skin the fruits in which yellow predominates over red seem to be in a heterozygous condition for yellow and red. Fruits in which red predominates are either homozygous or heterozygous, and the pure yellows are homozygous. No conclusive data were secured as to color of flesh, although crosses of Ben Davis and of McIntosh appear to carry yellow and white, the white being recessive.

Establishing laws of inheritance of size and shape in apples promises to be a difficult task, since these characters are subject to so many external conditions. The data at hand, however, indicate that size and shape are inherited

practically as intermediates. The study of the inheritance of sweetness and sourness was based wholly on crosses of subacid varieties. The total progeny indicates strongly that crosses of these subacid varieties break up in the proportion of 3 sour apples to 1 sweet one.

The authors call attention to the following difficulties likely to arise in the application of Mendelian principles in the breeding of apples: The determination of the factors by which the various characters are transmitted; complications arising when a character skips a generation—does not appear in the  $F_1$  generation; it is possible that some characters may be linked together in transmission and that others will repel each other; the bringing together of complementary characters may result in reversions and thus produce unexpected characters; the breeder will not be able to obtain new characters by working with Mendelian characters nor augment those that exist with the possible exception of size and vigor; it will be necessary to work with large numbers of plants—which is difficult with apples; disappointments will often come from the attempt to work with fluctuating variations; and there is likely to be much confusion between “simple Mendelian characters” and “blending characters.”

Some new apples from known parents, F. H. HALL (*New York State Sta. Bul.* 350, popular ed., pp. 12).—A popular summary of the above bulletin.

Apples of Missouri, W. W. CHENOWETH (*Ann. Rpt. Missouri Bd. Hort.*, 5 (1911), pp. 271-336, figs. 40).—This comprises descriptions of Missouri's most important varieties of apples. The material is compiled principally from The Apples of New York (E. S. R., 17, p. 1157), only such changes having been made as were deemed necessary to adapt the subject matter to Missouri conditions.

Artificial cross-fertilization of the mango, A. J. BROOKS (*West Indian Bul.*, 12 (1912), No. 4, pp. 567-569).—A preliminary experiment in the development of improved varieties of mangoes by cross-fertilization is briefly described.

Report of the assistant horticulturist, T. B. McCLELLAND (*Porto Rico Sta. Rpt.* 1911, pp. 28-31).—A brief statement of the station's work with coffee (E. S. R., 25, p. 746), vanilla, rubber (E. S. R., 25, p. 749), and cacao.

In addition to the old plantings of Porto Rican coffee a number of introduced coffees have now come into bearing. The coffee trees in the transplanting experiment begun in August, 1909, show a tendency toward earlier production where the trees were planted when less than a year old, and also where older trees were transplanted with a ball of earth. Storage and germination tests were conducted in 1909 and 1910 to determine whether the viability of coffee seed might be prolonged by excluding the moist air of the Tropics. In all these tests, the seeds which were very severely dried for any considerable length of time had their viability destroyed. A certain amount of moisture, as yet undetermined, appears to be necessary for its prolongation.

Experimental tapping of 8 to 9-year-old Castilla rubber trees gave only a slightly greater yield than that of the year preceding.

Fertilizers for carnations, D. LUMSDEN (*New Hampshire Sta. Bul.* 159, pp. 3-14, figs. 4).—This comprises a study of the relative value of nitrate of soda, muriate of potash, ground bone, a commercial fertilizer, and hen manure as top-dressings for carnation plants grown on raised benches in the greenhouse. Observations are also made relative to the difference in the keeping qualities of flowers raised under the various treatments given. Ground bone was found to give the best all around results, the vigor of the plants and the keeping qualities of the flowers being markedly superior to the plats treated with other manures.

**Spraying calendar for 1912**, R. K. BEATTIE and A. L. MELANDER (*Washington Sta. Popular Bul.* 43, folio).—Concise directions are given for the control of the more important insect pests and diseases of fruits and vegetables, together with instructions for making spray mixtures.

**Rules and regulations for carrying out the Plant Quarantine Act** (*U. S. Dept. Agr., Office Sec. Circ.* 41, pp. 12).—This circular contains the rules and regulations for carrying out the act of August 20, 1912, a summary of which has been previously noted (*E. S. R.*, 27, p. 494).

## FORESTRY.

**The profession of forestry**, H. S. GRAVES (*U. S. Dept. Agr., Forest Serv. Circ.* 207, pp. 17).—In this circular the author briefly reviews the rapid development of forestry in the United States and discusses forestry as a life vocation. Consideration is given to the character of the work involved, the elements necessary for success, the requirements for an adequate training, the present and probable future of recruits for government, state, and private work, teaching and research work, and its possibilities as a means of livelihood.

**Annual report on the progress, literature, and important happenings in the realms of forestry, hunting, and fishing for the year 1911**, H. WEBER (*Allg. Forst u. Jagd. Ztg.*, 1912, *Sup.*, pp. VIII+186).—As in previous years (*E. S. R.*, 26, p. 338), this supplement contains abstracts of the more important literature of the various phases of forestry, together with notes on the principal occurrences relating to forestry, hunting, and fishing during 1911. As in the last supplement, the international scope of the literature reviewed has been strengthened.

**Forestry and forest resources in New York**, F. A. GAYLORD (*N. Y. Conserv. Com., Div. Lands and Forests Bul.* 1, 1912, pp. 58, pls. 28).—This is a conservation bulletin, part 1 of which describes actual forest conditions in this country and especially in New York State, and points out the harmful results which have obtained through waste in exploitation and lack of protection. Part 2 discusses the future possibilities of the forests, outlines the principles of practical forestry, shows what forestry has accomplished in many other countries, and what can be accomplished in this country under proper management.

**Communication on the results of the Saxony state forest administration in 1911** (*Tharand. Forstl. Jahrb.*, 62 (1912), No. 4, pp. 373-377).—A statistical and financial statement of the work and results of the forest administration in 1911 with comparative data for 1910.

**On the influence of removing forest litter**, SCHWAPPACH (*Ztschr. Forst u. Jagdw.*, 44 (1912), No. 9, pp. 538-558).—The author has conducted observations for a great many years relative to the effect of removing forest litter on the growth of trees, as well as on the character of the undergrowth and the surface of the soil. The observations made in stands of pine, spruce, and beech, largely during the past 12 years, are here tabulated and discussed.

Generally speaking, removing the litter and raking the soil every year has been detrimental to wood accretion even on the better classes of soil. The decrease in wood accretion was also noticeable in stands where the litter was removed every 2 and 4 years. When the litter was removed only every 6 years, the loss in wood accretion was not great. Although removing the forest litter every year tends to stimulate natural regeneration, it also favors the growth of moss and other forest weeds. The injury to beech stands by a too frequent removal of litter was quite evident in the smaller growth of the leaves.

The woodsman's handbook, H. S. GRAVES and E. A. ZIEGLER (*U. S. Dept. Agr., Forest Serv. Bul. 36, rev., pp. 208, figs. 16*).—The present edition of this bulletin (E. S. R., 14, p. 576) has been revised and enlarged, taking the place of the proposed second part of the former bulletin and including both parts in one publication. The work as a whole comprises a collection of tables and rules of practical use to lumbermen, foresters, and others interested in the measurement of wood and timber. A summary of growth investigations is also included.

The Bradley bibliography, II.—Dendrology, Part II, A. REHDER (*Cambridge, Mass., 1912, vol. 2, pp. VIII+926*).—The present volume of the Bradley Bibliography (E. S. R., 26, p. 240) aims to contain the titles of all publications relating to families, genera, and species, together with references to descriptions, notes, and illustrations of woody plants contained in articles published in periodicals and serials and in smaller publications or in books dealing with subjects foreign to taxonomy where they are often apt to be overlooked.

Silvical leaflets (*U. S. Dept. Agr., Forest Serv. Silv. Leaflets 45, pp. 6; 51-53, pp. 4 each.*)—Four numbers of series of leaflets, each dealing with the range and occurrence, climate, associated species, habit, soil and moisture, tolerance, growth and longevity, susceptibility to injury, reproduction, utilization, and management of one of the following species of trees in the order corresponding to the leaflet numbers above: Western hemlock (*Tsuga heterophylla*), broadleaf maple (*Acer macrophyllum*), Oregon oak (*Quercus garryana*), and red alder (*Alnus oregona*).

Mechanical properties of redwood, A. L. HEIM (*U. S. Dept. Agr., Forest Serv. Circ. 193, pp. 32, figs. 8*).—This circular presents the results of one of the series of tests which the Forest Service has been making to determine the mechanical properties of the commercial woods of the United States (E. S. R., 25, p. 342; 26, p. 443). The tests here reported were conducted in cooperation with the universities of California and Washington.

The test material was divided into 2 classes, the first of which included stringers and joists containing defects similar to those present in timber purchased on the market. This material was tested to secure strength values for use in design, to find out whether there were differences in strength values of timber from different localities, and to determine the influence of seasoning and defects on the strength of commercial-sized timbers. The second class, made up of small, clear, straight-grained specimens cut from the uninjured portions of the tested stringers and joists, was tested to study the effects on their strength of the rate of growth, of the proportion of summerwood, and of the weight. Four kinds of tests were made to show strength in bending, in compression parallel to grain, in compression perpendicular to grain, and in resistance to shearing. The data secured in each of these tests are tabulated and discussed.

In conclusion the redwood lumber manufacturers' rules for grading are compared with a set of tentative grading rules for structural timbers prepared by the Forest Service.

The absorption of creosote by the cell walls of wood, C. H. TEESDALE (*U. S. Dept. Agr., Forest Serv. Circ. 200, pp. 7, fig. 1*).—Tests recently conducted by the Forest Products Laboratory and here tabulated and discussed show that a decided swelling takes place in wood impregnated with creosote. This swelling is caused by the absorption of the creosote by the cell walls. The average increases in volume resulting from the treatments of yew heartwood, yew sapwood, hemlock heartwood, and hard maple heartwood in percentage of the volumes before treatment were 6.81, 10.7, 7.3, and 8.14, respectively.

Condition of experimental chestnut poles in the Warren-Buffalo and Poughkeepsie-Newton Square lines after five and eight years' service, C. P.

WINSLOW (*U. S. Dept. Agr., Forest Serv. Circ. 198, pp. 13, figs. 2*).—This circular, which supplements a previous bulletin dealing with the preservative treatment of poles (*E. S. R.*, 25, p. 344), gives the results of inspections of 2 experimental lines, 5 and 8 years, respectively, after their establishment.

The poles for the Warren-Buffalo line were cut and peeled during 1902 and 1903 and seasoned in single tiers about 2 ft. above the ground in June and July, 1905. Some were butt-treated with various preservatives by the brush method and others with coal-tar creosote by the open tank method (*E. S. R.*, 19, p. 243). Six hundred and thirteen treated poles, together with 551 untreated seasoned and green poles were placed in a line extending through a variety of soil conditions.

At the end of 5 years both the green and seasoned poles butt-treated with coal-tar creosote by the open tank process showed practically no decay at or near the ground line. Poles brush-treated with 2 coats of coal-tar creosote, *Avenarius carbolineum*, *S. P. F. carbolineum*, and wood creosote showed but little difference in the extent of decay and ranked next best to the poles treated with coal-tar creosote in the open tank. Poles brush-treated with only 1 coat of preservative showed a much higher percentage of decay than those given 2 coats. With poles brush-treated with only 1 coat of creolin and of coal tar, the loss was nearly as great as with the untreated. The untreated poles were practically all more or less affected with decay at the ground line, the average loss of circumference for those seasoned prior to placement being 1.01 in. and for those placed green 1.15 in. An inspection relative to insect damage to poles in this line was made by the Bureau of Entomology and is discussed in a previous bulletin (*E. S. R.*, 25, p. 51).

Only 72 poles were placed in the Poughkeepsie-Newton Square line and records showing the details of their preparation and treatment are not available. As inspected after a lapse of 8 years, however, the untreated poles set in crushed stone showed less decay at the ground line than similar poles set in sand, the average loss of circumference at that point being 1.77 in. and 2.27 in., respectively. The poles with charred butts showed less decay at the ground line than similar uncharred and untreated poles set in either crushed stone or sand, their average loss in circumference at the ground being only 0.71 in.

## DISEASES OF PLANTS.

Report of the pathologist, G. L. FAWCETT (*Porto Rico Sta. Rpt. 1911, pp. 37-39*).—Spraying experiments with Bordeaux mixture on coffee trees were carried on with particular reference to its adhesiveness when used as a spray. Bordeaux mixture made up with but half the usual amount of water without the addition of any adhesives was found to adhere to the foliage better than Bordeaux mixture made by the usual formula to which adhesives were added.

A bud rot of the coconut has been found sporadically in a number of places but does not appear to be seriously affecting the groves. Bacteria have been isolated from the diseased tissue in every case studied, but no uniformity in the results of the studies has been obtained.

Work in soil biology has consisted largely in an examination of soils for protozoa, and in some of the so-called "sick" soils, where the conditions were the worst, the complete absence of protozoa was noted. Samples of these soils were disinfected with heavy applications of carbon bisulphid, but from the results of the study it appears that any benefit that is derived from the disinfection of the soils can not be attributed to the destruction of protozoa.

Root nodules were found to occur abundantly in the royal palm, and these have been studied with reference to their possible relation to nitrogen assimilation.

Where plants were grown in sterilized soil no fungus was found in conjunction with the nodules, but it was present in most of the other cultures, and except in the youngest nodules there was a rich development of proteids. Notes are also given on the occurrence of "air roots" on the royal and some other palms.

**New diseases of cultivated plants, A. PUTTEMANS** (*Bul. Soc. Roy. Bot. Belg.*, 48 (1911), No. 4, pp. 235-247, figs. 3).—Three diseases are reported from Brazil as found there, usually on introduced plants, rarely on native species. A spot disease of begonia is claimed to be due to a new fungus here described as *Oidium begoniae*. A cauliflower disease is ascribed to *Alternaria brassicae*. A parasite, found to cause a leaf spot of *Chrysanthemum indicum*, is described as a new species under the name *Cercospora chrysanthemi*.

**Plant diseases, 1909-10, A. OSTERWALDER and O. SCHNEIDER-ORELLI** (*Landw. Jahrb. Schweiz*, 26 (1912), No. 6, pp. 275-279).—A report is made concerning a large number of diseases due mostly to fungi noted in various localities as affecting fruit trees and fruits, grapes, vegetables, berry crops, and forest trees.

**The influence of nutrition and weather upon plant diseases, L. HILTNER** (*Jahrb. Deut. Landw. Gesell.*, 27 (1912), No. 1, pp. 156-169, pl. 1).—Details are given of studies on several crops, leading to the conclusion that the known relation between weather and certain plant diseases consists not alone in the influence of weather upon disease-producing agencies directly, but also in its influence upon the plant itself and especially upon its nutrition.

**The action of some acid salts upon the development of *Aspergillus niger*, A. KIESEL** (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 2, pp. 193-196).—A study was made by the author on the effects of 27 acids and acid salts on *A. niger* ascertaining in case of each the concentrations necessary to arrest, respectively, germination of conidia, development of mycelium, and fructification. The details are given in tabular form.

**Contribution to the study of the sooty molds, G. ARNAUD** (*Ann. École Nat. Agr. Montpellier, n. ser.*, 12 (1912), No. 1, pp. 23-54, figs. 13).—In extension of previous work (E. S. R., 25, p. 452), the author gives detailed results of his studies, both morphological and physiological, on a number of species of the sooty mold, including the relations of certain of these molds to honeydew.

**Studies in Chinese fungi, I. MIYAKE** (*Bot. Mag. [Tokyo]*, 26 (1912), No. 303, pp. 51-66, pl. 1; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 7, p. 1675).—Among the species of fungi discussed are many parasites of economic plants. Of these nine, claimed to be new, are described under the following names and in connection with the following hosts: *Cercospora alcuritidis*, on leaves of *Alcurites cordata*; *Helminthosporium sapii*, on leaves and leafstalks of *Sapium scbiferum*; *H. sesami*, on leaves of *Sesamum indicum*; *Brachysporium phragmitis*, on leaf nervures of *Phragmitis communis*; *Septoria amphigena*, on leaves of *Buplcurum falcatum*; *S. piri*, on leaves of *Pyrus sinensis*; *Nothopatella chinensis*, on branches of *Broussonetia papyrifera*, *Pruus persica*, and *Morus alba*; *Coniothyrium kraunhia*, on leaves of *Kraunhia floribunda*; *Macrophoma sophora*, on leaves of *Sophora japonica*; *Ustilaginoidca penniseti*, on glumes of *Pennisetum compressum*. Some of these are thought to be very destructive.

**A review of grain diseases, 1911, E. RIEHM** (*Centbl. Bakt. [etc.]*, 2, Abt., 34 (1912), No. 14-17, pp. 434-472).—This is a comprehensive review of the literature of grain diseases and pests during 1911, with an extensive bibliography covering the year.

**Control of loose smut of barley and wheat, R. SCHANDER** (*Kaiser Wilhelms Inst. Landw. Bromberg, Abt. Pflanzenkrank. Flugbl.*, 16, 1912, pp. 4, fig. 1).—This is a brief discussion of apparatus and methods for application of the hot-water

treatment to seed wheat and barley for protection against loose smut. See also a previous note (E. S. R., 24, p. 346).

**A rust-resistant hybrid wheat**, SCHIRIBAU (Bul. Soc. Nat. Agr. France, 72 (1912), No. 7, pp. 636-640).—The author gives an account of his attempts to secure by crossing a wheat resistant to the rust which annually attacks the grain in southeast France. He reports that a hybrid of Riète with Japhet responded best to these efforts, producing a wheat having comparatively few beards, exhibiting in fair degree the desirable features of earliness, quality, yield, and resistance to rust, and giving promise of future improvement in these respects.

**Dry spot of oats**, H. ZIMMERMANN (Mitt. Deut. Landw. Gesell., 26 (1911), No. 20, pp. 245, 246; abs. in Ztschr. Pflanzenkrank., 22 (1912), No. 4, p. 225).—The author sums up the results of observations made on dry spot of oats in the region of Mecklenburg, describing the appearance and progress of plants showing the disease. This is said to be of very variable severity, and to be probably due to excessive or improper liming in case of certain sandy or light soils of that region.

**Studies on canker in clover**, L. HILTNER and G. GENTNER (Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 10 (1912), No. 8, pp. 90-95).—This author claims that the appearance of clover canker, in most of the cases observed, was due to the use of imported seed and that different varieties of clover were affected in markedly different degrees. A brief discussion of the modifying effect on crop returns of climate and manures is also given.

**The prevalence of disease among varieties of sugar cane**, J. B. HARRISON and F. A. STOCKDALE (Jour. Bd. Agr. Brit. Guiana, 5 (1912), No. 4, p. 226).—The susceptibility of several varieties of Bourbon cane in regard to resistance to attacks of rind fungus is discussed.

**Canker or rot of Solanaceæ: Eggplant, peppers, and tomato**, P. VOGLINO (Italia Agr., 49 (1912), No. 3, pp. 56-58, fig. 1; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 4, pp. 1065, 1066).—*Ascochyta hortorum*, found in 1908 to cause a drying up of the leaves and fruits of eggplant, was in 1910 observed in France on stems of that plant. In the same year it was noted on tomato plants in Turin, the cankerous brown spots spreading from stalks and leaves to green or maturing fruits and darkening and rotting the pulp. Spraying with Bordeaux mixture proved an efficient remedy. The author offers the hypothesis that to this fungus also may be attributed the withering of peppers, producing much damage during recent years in Piedmont.

**Celery blights and how to control them**, E. M. STREIGHT (Veg. Grower, 2 (1912), No. 3, pp. 4, 16, figs. 7).—An account is given of the appearance, mode of attack, and progress of *Cercospora apii* and *Septoria petrosclini*, said to cause, respectively, early and late blight of celery. Spraying with the usual Bordeaux mixture is claimed to prevent both spread and infection, if used in time.

**Some apple diseases and their treatment**, C. BROOKS (New Hampshire Sta. Bul. 157, pp. 32, figs. 30).—This is a revised edition of Bulletin 144 of the station (E. S. R., 22, p. 747), with some additional information relating to the fruit spot of the apple due to *Phoma pomi*, a preliminary account of which has been noted (E. S. R., 27, p. 652).

**[Diseases of peaches in the Caucasus and resistant varieties]**, A. S. BONDARTSEV (Zhur. Boliezni Rast., 5 (1911), No. 5-6, pp. 134, 135; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 4, p. 1061).—Among the causes of diseases attacking peaches in the Caucasus region in 1911 are mentioned *Eoascus deformans*, *Cercospora cerasella*, *Puc-*

*cinia pruni-spinosa*, *C. persica*, *Sphaerotheca pannosa*, and *Monilia fructigena*. Varieties of peaches found resistant are named in connection with each of the first three fungi above listed.

**A contribution to the study of olive rot**, G. DE MICHELE (*Bol. Arbor. Ital.*, 7 (1911), No. 3-4, pp. 179-192, figs. 7).—This disease is said to affect old olive trees of diminished vitality, or young trees in consequence of injuries of improper culture. These conditions favor the activity of bacteria which produce changes in the living tissue followed by gradual death of the tree, the details of the process not yet being beyond dispute.

Incipient appearances are said to be subdued by cutting out cleanly the affected parts and thoroughly disinfecting the wounds. For more advanced stages a similar but more radical treatment is prescribed. Remedial measures looking to the preservation of vigor in the trees are also recommended.

**Eruptive disease, or "exanthema," of orange trees in Australia**, C. C. BRITTELBANK (*Jour. Dept. Agr. Victoria*, 10 (1912), No. 7, pp. 401-404, figs. 2).—The author briefly describes this disease, which is claimed to be physiological and to be due primarily to weakened vitality. This weakening is attributed generally to porous, deep, coarse, sandy soil, lacking in organic matter, drying out quickly after rain; to continued drought followed by heavy rain; and to the presence of large amounts of nitrogenous manures.

Remedial measures suggested include the plowing in of green crops previously manured with superphosphates, and avoidance of nitrogenous manures.

**Permanganate of potash in viticulture**, C. TRUCHOT (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 34, pp. 229-231).—The author recommends as a remedy for a gray rot of grapes, ascribed to *Botrytis cinerea*, a mixture of 15 parts of permanganate of potash with 85 parts of sifted lime, applied in powdered form, preferably after rain or a heavy dew. In a second formula, 5 per cent of alum replaces an equal proportion of the permanganate. The action is claimed to be certain.

**Grape chlorosis and its treatment with sodium nitrate and iron sulphate**, E. CHANCRIN (*Jour. Agr. Prat., n. ser.*, 23 (1912), Nos. 22, pp. 683-686; 23, pp. 715, 716).—Chlorosis of grape leaves is here held to be due in general to poor nutrition, most commonly with lime as a primary injurious factor assisted by various secondary conditions.

Experiments were conducted under direction of the author in treating seriously affected vines with solutions of sulphate of iron and nitrate of soda. The iron salt did not give very good results. The treatment with nitrate of soda in most instances showed considerable improvement, and in many cases complete recovery, where the dose amounted to 25 or 30 gm. per stock.

**The subsequent influence of fungicides on the vigor and production of grapevines, and their resistance to chlorosis**, J. L. VIDAL (*Rev. Vit.*, 37 (1912), No. 965, pp. 813-818, figs. 2; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 8, pp. 1887, 1888).—The experiments reported are said to indicate that mildew exercises a more or less remote influence on grapevines, as shown by the reduction of resistance to chlorosis, weakening of vegetation, and lowering of productivity, these influences being somewhat proportional to the damage inflicted at any given time by the fungus, early invasions usually resulting in greater subsequent damage to the vines.

The author concludes that protection by spraying should extend not only to present crops but to vines with a view to future returns, even light attacks of mildew being carefully guarded against for the sake of greater vigor in the vines.

The conditions for development of grape mildew, L. RAVAZ and G. VERGE (*Les Conditions de Développement du Mildiou de la Vigne. Montpellier, 1912, pp. 61, figs. 9*).—The authors here present in connected form the results of their studies on the conditions controlling the development of grape mildew, most of which have already been previously noted (E. S. R., 27, p. 449).

Third year's experiments in the treatment of grapevine mildew in the Bombay Presidency, W. BURNS and G. B. PATWARDHAN (*Dept. Agr. Bombay Bul. 51, 1912, pp. 6*).—In the third year of experimenting for the control of grape mildew (E. S. R., 27, p. 49) sprayings from 3 to 5 in number were given in 3 districts. The resulting percentages of mildewed grapes ranged from 1.7 to 21, averaging 9.7 per cent, for sprayed vines; and from 42 to 100 per cent, averaging 68.8 per cent, for unsprayed vines. The sprayings recommended employ Bordeaux mixture of full strength about the middle of May, August, and October, and of half strength again about the first of December and January with plenty of soap to make the fungicide stick to the bunches.

The amount of copper left on the grapes was not considered deleterious to users and the stains were found to be easily removable by simply dipping in weak vinegar or soaking in clean water over night.

A new plan of attack on grape mildew, H. FAES (*Bul. Soc. Agr. France, 1912, May 15, pp. 513-523*).—The substance of this article has already been noted (E. S. R., 26, p. 550).

The spread of American gooseberry mildew, S. CASTLE (*Gard. Chron., 3. ser., 52 (1912), No. 1338, p. 138*).—The author reports that in the neighborhood of Wisbech the American gooseberry mildew is making rapid headway in spite of all efforts looking toward its control.

Two fungus diseases of tulip bulbs, A. A. ELENKIN (*Zhur. Boliczni Rast., 5 (1911), No. 5-6, pp. 105-124; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases, 3 (1912), No. 4, pp. 1066, 1067*).—Tulip bulbs were attacked by two different fungi, the first being recognized as *Botrytis cinerea*, the second in form and habits somewhat resembling *Sclerotium tuliparum*, and possibly being identical therewith. The two are usually found on the same bulb, rarely attacking separate plants. Methods of control recommended are uprooting and burning of affected bulbs, and disinfection of the soil with carbolineum.

A new bacterium causing a disease of *Matthiola annua*, G. BRIOSI and L. PAVARINO (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 21 (1912), II, No. 3, pp. 216-220*).—A disease of *M. annua* is described which, it is said, may extend to any part of the plant. A bacterium was isolated and cultivated to which the disease is ascribed. The organism is claimed to be new and has received the name *Bacterium matthiolæ*.

Observations on *Asarum europæum* and its mycorrhiza, E. J. SCHWARTZ (*Ann. Bot. [London], 26 (1912), No. 103, pp. 769-776, pls. 2*).—As a result of the author's investigations, it is stated that *A. europæum* harbors in its roots a fungus very similar to those of *Thismia aseroë* and *Nectria nidus-avis*, and limited to the cortical region abutting on the steles of the young roots. Thick-walled swellings found on some hyphæ are said to represent a resting stage of the fungus. A bibliography is appended.

Knobs and exostoses on trees, E. LEMÉE (*Rev. Hort. [Paris], 84 (1912), No. 14, pp. 336-338, figs. 16*).—Attention is called to various kinds of swellings and excrescences on roots, trunks, limbs, and twigs of certain trees, known or suspected to be due to the activity of fungi or other parasites.

Studies on gum flow and frost injuries of various trees, II, P. SORAUER (*Landw. Jahrb., 41 (1911), No. 1, pp. 131-162, pls. 2; abs. in Bot. Gaz., 54 (1912), No. 2, pp. 173, 174*).—In continuation of previous work on the factors

operative in gummosis (E. S. R., 23, p. 353; 24, p. 554), the author holds that stimuli, such as frosts and wounds, only accentuate a natural tendency latent in cherry and other trees to gummy degeneration and related phenomena due to variations in growth and nutrition which may be regarded as not abnormal. These may result in cell immaturity, unbalanced tensions, excess of enzymes, and degeneration processes extending from cell to cell. Such groups of degenerated cells are usually more abundant in the late fall growth. Looseness of structure appeared to be closely related with susceptibility to frost influence and formation of gum.

Detailed studies were made of numerous widely separated genera of trees.

**The Pennsylvania Chestnut Blight Conference** (*Harrisburg: State, 1912, pp. 253, pls. 43*).—This is a report of the proceedings of a conference, called by the Governor of Pennsylvania to meet at Harrisburg, Pa., February 20 to 21, 1912, to consider ways and means of preventing the spread of the chestnut tree bark disease. An address by the governor, and numerous papers, reports and discussions by scientists, foresters, manufacturers, and others, bring out what was known at that date and what it was considered should be known concerning this disease.

**Notes on the chestnut bark disease, H. R. FULTON** (In *Pennsylvania Chestnut Blight Conference, Harrisburg: State, 1912, pp. 48-56*).—The author reports on a study of the means, methods, and conditions of transmission of this disease, in substance briefly as follows:

The infective material in case of *Diaporthe parasitica* consists in its conidia and its ascospores. Tests made with air currents as carriers of conidia, dry, damp, and under strong spraying to simulate storm conditions, showed that conidia can be detached by strong air blasts and carried short distances. Conidia in a dry room at ordinary temperature, retained their germinability for four months, but not for five, while material exposed out of doors and that kept moist at about 75° F. in a greenhouse did not germinate after four months. Both kinds of spores germinated in a decoction of chestnut bark, in rice broth, etc. Ascospores germinated in spring water, while conidia did not. Germinability of conidia is most favored at 60°, decreasing considerably at 10° above or below that point. Ascospores germinated best at 70°, but also fairly well at 45° or 85°, and they still germinated readily after at least moderate freezing. The effect of extreme temperatures was not investigated. In general, the most rapid early growth is at the optimum temperature for germination.

In the laboratory the fungus grows well on a variety of artificial media, particularly on a slightly acid potato agar. Some evidence seems to point to the possibility of its living on at least dead parts of trees other than chestnut, as oaks, etc., though such have not been shown to be diseased by the fungus. Infections were found where injuries to chestnuts had been inflicted by lightning, etc., both sapwood and heartwood becoming infected by spreading of the fungus if the cut surface was kept moist. Insect injuries also appeared to be favorable points for development of infection from spores. Field studies at Orbisonia, Pa., seem to indicate that there had been a very rapid spread of the disease recently; that insects may carry infection up the branches and into the cracks and holes; that moisture favored infection in certain cases; that younger trees were more susceptible than older ones; and that birds were not notably, if at all, connected with the carrying of spores.

**[Longevity of mycelium and spores of *Diaporthe parasitica*], CAROLINE RUMBOLD** (In *Pennsylvania Chestnut Blight Conference, Harrisburg: State, 1912, pp. 241, 242*).—An attempt was made to germinate spores from an infected piece of chestnut collected in July, 1908, and kept continuously in a moist cell until April, 1912. The fungus made a small growth, but after start-

ing to produce a small number of pycnidia it ceased to grow. Spores also germinated, but these too made only a small growth, producing no pycnidia. The apparent loss of vitality, it is suggested, might have been due to *Penicillium*, a growth of which covered the surface of the specimen.

The possibility of a medicinal remedy for chestnut blight, CAROLINE RUMBOLD (In *Pennsylvania Chestnut Blight Conference, Harrisburg: State, 1912*, pp. 57, 58).—The author reports in regard to medicinal treatment of chestnut blight that experiments are under way, but are as yet incomplete, considering the influences of soil and atmospheric moisture, of fertilizers, of healthful or unhealthful surroundings and conditions of the tree, of wounds, etc., on the susceptibility of the tree to disease, and on its reaction to treatment. She states also that experiments to test the relative vitality of the mycelium and of the two kinds of spores and others with chemicals toxic to the fungus are in progress, as well as studies on the question of immunity of different kinds of trees.

The biological relations of *Rhytisma acerinum* to various maples, K. MÜLLER (*Ber. Dcut. Bot. Gesell., 30 (1912), No. 7, pp. 385-391*).—The author investigated *R. acerinum* for the purpose of determining whether or not this fungus is to be classed as a single species. Inoculation experiments were carried on with several species of maple in the open air during 1908-1911 with the following results:

Spores from *Acer platanoides*, which is widely distributed, easily infected this maple and *A. campestre*, but, in general, only partially and weakly *A. pseudoplatanus* and *A. dasycarpum*.

Morphologically similar fungi from *A. pseudoplatanus* from several localities severely infected the same maple in the locality of the experiment, while the other species of maple were not attacked at all. This biologically distinct species of fungus was named *R. pseudoplatani*. *R. punctatum*, which is claimed to be limited to *A. pseudoplatanus*, is morphologically distinguished from *R. pseudoplatani* by its larger sclerotia and spores.

Spores from the fungus on *A. campestre* attacked this maple severely, less so *A. platanoides*, and not at all *A. pseudoplatanus*. The fungus is considered to be a specialized form of *R. acerinum*, less distinct than is *R. pseudoplatani*, and to it the name *R. acerinum campestre* is given. Further reports are promised on the morphological relations of *R. acerinum*.

Oak disease in 1909 and 1910, É. PAQUE (*Bul. Soc. Roy. Bot. Belg., 48 (1911), No. 1, pp. 22-26*).—A brief account is given of the oak disease due to *Oïdium* in France. During 1909 and 1910 its intensity is said to have diminished somewhat in that section. Lists are given of the species of trees attacked and those exempt. Attention is drawn to the fact that, while almost every native oak was attacked, nearly all foreign species in the same forests appeared resistant to this fungus.

The oak *Oïdium* in France, G. TRINCHIERI and L. MANGIN (*Jour. Agr. Prat., n. ser., 23 (1912), Nos. 16, pp. 496, 497; 23, pp. 719-721*).—This is a continuation of contributions made by these authors and by G. Arnaud and E. Fœx on oak *Oïdium* (*E. S. R., 20, p. 757; 23, p. 354; 25, p. 248; 27, p. 753*), the later discussions being somewhat controversial.

Oak *Oïdium* in Sologne, E. NOFFRAY (*Bul. Soc. Nat. Agr. France, 72 (1912), No. 7, pp. 575-584*).—An account is given of the appearance of oak *Oïdium* in Sologne in 1907 and of its progress, habits, and damage in that district.

It is stated that but slight infection by this fungus is noted in growths of 4 years and over, but that it severely attacks the younger trees and branches. From this fact it is concluded that this fungus may be checked, possibly exterminated, in a few years by sacrificing these younger growths for a while, if

necessary, and by early and free use of such fungicides as sulphur, polysulphids, and permanganate of potash with a view to prevention rather than cure.

**A root disease of the Para rubber tree (*Fomes semitostus*), K. BANCROFT** (*Dept. Agr. Fed. Malay States Bul. 13, 1912, pp. 30, pls. 79*).—This is a brief discussion of the history, distribution, spread, symptoms, and treatment of the root disease of *Hevea brasiliensis* and of its relation to other hosts and to attacks by insects.

The disease attacks the roots, cutting off the water supply, yellowing and wilting the leaves, and killing the trees in from 4 months to 2 years according to age. The fungus seems to propagate itself mainly by means of mycelium which spreads in the roots, living or dead, also to some extent in the soil, attacking live roots of young or old trees, but soon disappearing if left without its customary substratum.

Moisture, abundance of vegetable matter, acidity of soil, and darkness favor mycelial growth. Experiments with artificial infections by means of mycelium were successful in 10 out of 14 plants tried. Infection of living plants from dead roots is thought to be the usual mode of transmission. Spores arise from two forms of fructification, but are not known to carry the disease. Several other hosts are known, all being woody plants.

Methods of treatment include isolation by means of trenches; sanitation by removal or burning in place of all infected or suspected trees or parts; application of lime to neutralize acidity, and possibly as a fungicide; drainage; and utilization of the space with immune trees, while the infected roots of the removed trees are disappearing from the soil.

A brief bibliography is appended.

**Two new diseases of *Sophora japonica*, M. TURCONI and L. MAFFEI** (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 21 (1912), II, No. 4, pp. 246-249*).—This is a preliminary note descriptive of two new fungi, which have received the names *Macrosporium sophoræ* and *Gibberella briosiana*, attacking, respectively, leaves and branches of the pagoda tree of China and Japan.

**A case of gummosis in teak, J. A. HONING** (*Meded. Deli-Proefstat. Medan, 7 (1912), No. 1, pp. 12-15, 59*).—An account is given of the evident infection of teak nursery stock with *Bacillus solanacearum*, causing gummosis, this being claimed to be the first instance in which this plant has been attacked by this disease.

**Macrophoma excelsa infestans parasitic on *Abies concolor* in Russia, I. A. OHL** (*Zhur. Boliczni Rast., 5 (1911), No. 5-6, pp. 127-134, pl. 1, figs. 2; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases, 3 (1912), No. 4, pp. 1067, 1068*).—In Poltava *A. concolor* showed disease due to a parasite identified as a *Macrophoma*, for which the author suggests the name *M. excelsa infestans*. The use of fungicides in spring, and burning and removal in autumn, are remedial measures recommended.

**Lophodermium nervisequum parasitic on fir needles, E. MER** (*Bul. Soc. Nat. Agr. France, 72 (1912), No. 7, pp. 615-625; Rev. Eaux et Forêts, 51 (1912), No. 16, pp. 481-493, pl. 1*).—Pursuant to studies previously noted (*E. S. R., 25, p. 47; 26, p. 451*) with *L. macrosporum* on spruce, the author reports his investigations with *L. nervisequum*, parasitic on fir, which it is said to attack when meeting it in a state of deficient nutrition, and causing, as does *L. macrosporum*, considerable loss in France. Experiments seem to show the protective value of keeping trees well nourished and vigorous.

**Root disease of pine, M. MANGIN** (*Compt. Rend. Acad. Sci. [Paris], 154 (1912), No. 23, pp. 1525-1528*).—The author made a study of this disease, of the fungus (*Rhizina inflata*) said to cause it, and of the effects of forest fires

which are claimed to favor its attacks. As a result of these investigations, the conclusions are reached that *R. inflata* is common even on sound trees throughout the pineries of Fontainebleau; that the development of the fruiting bodies is favored by the fertilizing constituents of ashes left by forest fires and woodmen's fires; and that it is at present doubtful whether the disease is caused by invasion of the pine roots by the mycelium of *R. inflata* which, according to the author, occurs rather after the weakening of the tree by the disease, the reason of which he claims to be at present unknown.

**Experiments in spraying with polysulphids and other fungicides in 1911.** E. PANTANELLI (*Staz. Sper. Agr. Ital.*, 45 (1912), No. 3, pp. 161-190).—The author's experiments resulted in the following conclusions:

The polysulphids of calcium, barium, and zinc with sodium have shown an efficacy equal or superior to that of Bordeaux mixture in controlling *Eroscus deformans* and other fungus diseases of peach and apple. They have also been used with success against *Oidium* of rose, oak, and euonymus, against *Exobasidium azalea*, etc. These polysulphids and combinations thereof with Bordeaux mixture, acetate of copper, and nitrate of silver are recommended as efficacious also against *Peronospora* and *Oidium* of the grape. The polysulphids of barium and zinc with sodium are said to show a stimulating action on vegetation, especially that of peaches, and to be harmless to both leaves and flowers, whereas those of calcium are fatal to the foliage of the peach. The question of relative cost is also discussed.

[The mechanical reduction of spray particles], P. LARUE (*Rev. Vit.*, 37 (1912), No. 967, pp. 879-881, figs. 5).—This is a report on experiments made with nozzles of various forms, but having orifices mainly cylindrical with a conical flare.

It is stated that no conclusions have been drawn as to the best form, but that a suitable smallness of droplets could not be attained at a shorter distance than 50 cm. from the nozzle. This fact is said to be an obstacle to the employment of devices for spraying stems, branches, and lower leaf surfaces with the maximum of economy as regards liquid and labor.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

**Distribution and origin of life in America.** R. F. SCHARFF (*London, 1911*, pp. XVI+497, pls. 21).—The chapters of this work are devoted to the fauna of Greenland, the fauna of northeastern North America, the animals of the Canadian Northwest, the fauna of Alaska, the Rocky Mountains and their inhabitants, the animals of the Eastern States, the fauna of the Continental Basin, the Southeastern States and Bermuda, southwestern North America and its fauna, the fauna of Central America, the West Indian Islands and their inhabitants, the fauna and flora of the Galapagos Islands, the animals of the northwestern States of South America, the fauna of eastern South America, and Argentina and Chile.

A bibliography of the principal works consulted in its preparation, consisting of 32 pages, and a general index are included.

**Food of some well-known birds of the forest, farm, and garden.** F. E. L. BEAL and W. L. MCATEE (*U. S. Dept. Agr., Farmers' Bul. 506*, pp. 35, figs. 16).—This bulletin deals with 20 birds selected because of their economic importance to farmers and fruit growers of the respective regions they inhabit. With the exception of 3 species of sapsuckers, all the birds treated are beneficial and should be recognized and protected. The species considered are, the three-toed woodpeckers (*Picoides arcticus* and *P. americanus*); California woodpecker (*Melanerpes formicivorus bairdi*); Lewis woodpecker (*Asyndesmus*

*levisi*); red-bellied woodpecker (*Centurus carolinus*); sapsuckers (*Sphyrapicus varius*, *S. ruber*, and *S. thyroideus*); hummingbirds (*Archilochus colubris* and *Calypte anna*); Arkansas kingbird (*Tyrannus verticalis*); ash-throated flycatcher (*Myiarchus cinerascens*); western yellow-bellied flycatcher (*Empidonax difficilis*); horned lark (*Otocoris alpestris*); chipping sparrow (*Spizella passerina*); junco or snowbird (*Junco hyemalis*); white-crowned sparrow (*Zonotrichia leucophrys*); southern butcher bird (*Lanius ludovicianus*); Audubon warbler (*Dendroica auduboni*); and ruby-crowned kinglet (*Regulus calendula*).

Fish and game laws of New Jersey (Trenton, N. J., 1912, pp. 232, pl. 1).—This is a compendium of the New Jersey laws.

Capture of Raleigh by the wharf rat, C. S. BRIMLEY (*Jour. Elisha Mitchell Sci. Soc.*, 28 (1912), No. 2, pp. 92-93).—The author reports that while known to have been at Beaufort in 1870, the wharf rat was not observed in Raleigh until 1909. Two years later it appeared in great abundance and slaughtered large numbers of young chickens. The wharf rat is strongly inclined to burrow, while the black and brown rats are climbers.

Life histories of Indian insects, II, D. NOWROJEE (*Mém. Dept. Agr. India, Ent. Ser.*, 2 (1912), No. 9, pp. 165-191, pls. 7, figs. 2).—A number of aquatic Hemiptera and Coleoptera are taken up in this second paper (*E. S. R.*, 24, p. 75S).

Recent investigations in insect parasitism, O. H. SWEZEY (*Hawaii. Forster and Agr.*, 9 (1912), Nos. 3, pp. 83-87; 4, pp. 130-135).—A review of recent work.

The effect of heat on certain insect enemies of plants, J. CHAINE (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 26, pp. 1833-1836).—High temperatures during the latter part of June and early July, 1911, when the thermometer reached 37° C. (98.6° F.) in the shade, together with a prolonged drought, resulted in the destruction of larvæ and chrysalids of the cochyliis moth to such an extent that in certain regions the second generation was nearly completely annihilated. The cecidomyid *Nourthropalpus buri*, which develops in boxwood leaves, is said to have been similarly destroyed.

Report of the entomologist, W. V. TOWER (*Porto Rico Sta. Rpt. 1911*, pp. 32-36).—The work of the year consisted largely of the study of the white grub on cane and an ant which infests coffee and practically all its shade trees. A mosquito survey of San Juan was commenced.

In a study of the flora of practically all districts of the island, undertaken since the bee work previously noted (*E. S. R.*, 26, p. 62), a great number of shade trees used in coffee plantations have been found to produce nectar. In the lowlands guamá (*Inga laurina*), which is by far the best honey plant on the island, is used almost entirely, while in the interior the guava is the principal shade tree in coffee plantations. It is said to be not uncommon for a good strong hive of bees to gather from 5 to 11 lbs. a day from the guamá, which blossoms from 2 to 5 times a year, the bloom lasting from 10 to 15 days. The honey produced is very light in color, resembling the clover honey of the North and running about 12 lbs. to the gallon.

In order to determine the annual production of honey by a good colony, 2 colonies were placed on a pair of scales and their weights taken morning and evening. "The readings showed at what seasons the bees were most active; also what flowers produced the greatest quantity of honey. During a period of 9 months from one of the colonies there were extracted 470 lbs. of honey, while the other produced 337 lbs. The only period when both colonies were not gathering was during September, and during this month the small colony gathered sufficient honey so that it did not have to use any of its surplus. Beginning the latter part of February and through March, April, and May, the bees worked on the general bloom, and it was not uncommon for them to gather

from 1 to 2 lbs. of honey per day." During July and August one of the hives gathered 203 lbs. of honey.

While the native mangoes, with one exception, are comparatively free from insect infestation some of the imported varieties appear to be seriously attacked by the fruit fly (*Anastrepha acidusa*). This fly is very partial to the Cambodiana, practically ruining this variety, it being almost impossible to find a ripe mango that does not contain from 2 to 5 maggots. Upon completing their development the maggots pass into the ground to a depth of 1 to 1½ in. where they pupate in about 24 hours, the pupal period lasting from 13 to 16 days.

A small white scale, which occurs in India, was found on the trunks and large branches of the mango but does not seem to spread rapidly in Porto Rico. At Mayaguez this scale has been found parasitized by the common black fungus, occurring on the white scale of the orange, and a brown fungus which is found on the purple scale in the mountains. Thrips are said to be plentiful on some varieties of mangoes, especially those infested by the fruit fly.

Reports of entomological department, A. E. STENE ET AL. (*Ann. Rpt. Bd. Agr. R. I., Ent. Dept., 25 (1910), pp. 40+11+39, pls. 7, figs. 21*).—The several parts of this report deal with nursery inspection, insect notes, report of apiary inspection, the gipsy and brown-tail moth situation, the elm-beetle and San José scale work, bee keeping in Rhode Island, and how to keep bees.

Combating scale and other insects, L. TRABUT (*La Défense contre les Cochenilles et autres Insectes Fixés. Algiers: Gourt. Gén. Algérie, 1910, pp. 151, pls. 4, figs. 127*).—Noted from another source (*E. S. R., 27, p. 357*).

Insect pests, J. H. FABRE (*Les Ravageurs; Récits sur les Insectes Nuisibles a l'Agriculture. Paris, [1912], pp. 282, pls. 16*).—This is a small popular work.

Sugar cane insects in Trinidad, F. W. URICH (*West Indian Bul., 12 (1912), No. 3, pp. 388-391*).—The principal cane pests and their status in Trinidad are briefly noted.

The enemies of the olive, P. PAPAGEORGIU (*Ann. Gemblour, 22 (1912), No. 9, pp. 521-531*).—The author here gives a brief account of the olive scolytid (*Phlæotribus oleæ*), olive fly (*Dacus oleæ*), olive scale (*Lecanium oleæ*), and sooty mold (*Fumago oleæ*), and means of combating them.

Insects attacking the prune in the Pacific Northwest, A. B. CORDLEY (*Better Fruit, 7 (1912), No. 2, pp. 9-13, figs. 6*).—This is a brief popular account of the more important insect enemies of the prune, including the western peach and prune borer (*Sanninoidea opallescens*), San José scale, prune twig miner (*Anarsia lineatella*), bud-moth, shot-hole borer (*Xylcborus dispar*), cicadas, the branch and twig borer (*Polycaon confertus*), and tent caterpillars (*Malacosoma* spp.).

Natural enemies of the banana occurring in Queensland, H. TRYON (*Queensland Agr. Jour., 28 (1912), No. 5, pp. 360-363*).—The insect pests here mentioned are the fruit fly *Dacus (Tephritis) tryoni* and a leaf-eating weevil (*Coptorhynchus* sp.).

Insect pests of cacao, P. L. GUPPY (*West Indian Bul., 12 (1912), No. 3, pp. 310-320*).—In addition to a somewhat detailed account of the cacao beetle (*Steirastoma depressum*) and cacao thrips (*Heliothrips rubrocinctus*), the author presents a preliminary list of 30 insects affecting the cacao tree, arranged more or less in the order of their importance.

Coconut pests, O. W. BARRETT and D. B. MACKIE (*Philippine Agr. Rev. [English Ed.], 5 (1912), No. 5, pp. 254-261, pls. 5*).—This is a brief account of the enemies of the coconut, including insects, diseases, mammals, birds, and Crustacea.

It is said that of 75 or more recorded insect pests of coconut there are only 5 or 6 species that are actually injuring the crop to any great extent and of these

only 2 are of prime importance in the Philippines. "Throughout the Philippine Archipelago, and in fact in all southern Asia and the Malaysian regions, the mang. or rhinoceros beetle (*Oryctes rhinoceros*) causes a tremendous amount of damage. . . . The red weevil (*Rhynchophorus ferrugineus*) is the second most destructive insect attacking coconuts in the Philippines."

The enemies and diseases of the coffee tree in East Africa, H. MORSTATT (*Pflanzcr.*, 8 (1912), *Beiheft* 2, pp. V+87, pls. 14).—The first part of this paper (pp. 1-74) is devoted to a discussion of the various animal enemies of the coffee tree, of which the insects make up the greater part.

Forest entomology in the United States, K. ESCHERICH (*Naturw. Ztschr. Forst u. Landw.*, 10 (1912), No. 9, pp. 433-446, figs. 4).—This is a review of the work carried on by the forest insect division of the Bureau of Entomology of this Department, and includes a list of the more important writings on the subject by A. D. Hopkins.

Tetriginæ (Acridiinae) in the Agricultural Research Institute, Pusa, Bihar, with descriptions of new species, J. L. HANCOCK (*Mem. Dept. Agr. India, Ent. Ser.*, 4 (1912), No. 2, pp. 131-160).—Some 24 species are described as new in this paper.

A new pest to maize, C. FRENCH, JR. (*Jour. Dept. Agr. Victoria*, 10 (1912), No. 7, pp. 450, 451, figs. 2).—The harlequin fruit bug (*Dindymus versicolor*) is reported to have been the source of injury to corn at Omeo, Gippsland. The injury is caused by sucking the juice from the kernels at the end of the cob.

A note on acid-fast bacilli in head lice (*Pediculus capitis*), G. W. MCCOY and M. T. CLEGG (*Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Rpts.*, 27 (1912), No. 36, pp. 1464, 1465).—In recent work in connection with the study of the possibility of the transmission of leprosy by animal parasites, the authors have found a large number of acid-fast bacilli in smears made from 2 lice (*P. capitis*) taken from an advanced case of nodular leprosy. In morphology, grouping, and tinctorial characteristics, the organisms found in these insects were indistinguishable from the leprosy bacillus.

Leafhoppers affecting cereals, grasses, and forage crops, H. OSBORN (*U. S. Dept. Agr., Bur. Ent. Bul.* 108, pp. 123, pls. 4, figs. 29).—This bulletin is based upon investigations made in the field, on farms and ranges, under natural conditions in various parts of the United States, and deals particularly with those species affecting the cultivated crops.

On grasses and grains the attack is more commonly noticed in the form of wilted or discolored blotches on the leaves or stems. The author believes that the condition known as "silver top," a whitening of the entire upper part of stem and head, is at times, in blue grass particularly, caused by leafhopper attack. The puncturing of the tissue and pumping of the plant juices result in more or less loss and drain on the plant, the importance of the attack depending upon the abundance of the insects. "All of the crops belonging to the grass family and most of those in general cultivation belonging to the legumes are infested by one or another, often by many, species of the leafhoppers. The abundance and corresponding injury vary greatly with these crops for different parts of the country and under different cultural conditions, as also with different seasons. . . . For the wheat, oats, rye, and barley crops the most important species are, in the North and Northwest, *Cicadula 6-notata* and *Athysanus exitiosus*, and in the South *A. exitiosus* and *Dræculacephala reticulata*. For the grass crop, including timothy, brome grass, and blue grass, the most important species are *Deltocephalus inimicus*, *D. affinis*, *D. configuratus*, *Dræculacephala mollipes*, and *Phlepsius irroratus*. For clover, alsike, alfalfa, soy beans, and leguminous crops the most important are *Agallia sanguinolenta* and *Empoasca mali*. The

fact that in many parts of the country their injury is negligible for such crops as wheat, oats, rye, etc., is due to the rotation or alternation of crops in such manner as to make their rapid increase impossible."

Other species considered in addition to the above mentioned are *Drædacephala norcaboracensis*, *Diædrocephala coccinea*, bog leafhopper (*Hætochara communis*), *Gypsona octolineata*, *G. bimaculata*, *Tettigonia bifida*, *Heccalus lineatus*, shovel-nosed leafhopper (*Dorycephalus platyrhynchus*), *Parabolo-cratus viridis*, sharp-nosed leafhopper (*Platymetopius acutus*), yellow-faced leafhopper (*Platymetopius frontalis*), *P. cinereus*, *Deltocephalus sonorus*, *D. fuscinerrosus*, Say's leafhopper (*D. sayi*), *Athysanus curtisii*, *A. bicolor*, *A. obtutus*, and geminate leafhopper (*Thamnotettix geminatus*).

Remedial measures are discussed under the headings of cultural methods, mowing, burning, capturing in hopperdozers or tar pans, and spraying, all of which must be adapted for the seasons or conditions of the crop.

What are we going to do about the froghopper? J. J. A. CARLEE (*Proc. Agr. Soc. Trinidad and Tobago*, 12 (1912), No. 8, pp. 265-272).—A discussion of the present status of the froghopper situation in Trinidad.

The spring grain-aphis or "green bug," F. M. WEBSTER and W. J. PHILLIPS (*U. S. Dept. Agr., Bur. Ent. Bul.* 116, pp. 153, pls. 9, figs. 53).—This is a complete report of investigations commenced in the spring of 1907 and continued without interruption up to and including 1911. Preliminary reports upon the work have been previously noted (*E. S. R.*, 19, pp. 53, 452).

The authors first consider the occurrence of the pest in the Old and New World. In the United States outbreaks occurred in 1890, 1901, 1903, and 1907. Then follow accounts of its food plants, character of attack, viviparous and oviparous development, influence of winds and of temperature on diffusion, its embryology, natural enemies, and remedial and preventive measures.

Field spraying experiments indicate spraying to be an impractical measure, even when small areas are involved. Burning or plowing are thought to be more effective. Lime and sulphur dusted on the plants in badly infested areas gave practically no benefits. It is recommended, especially for the South, that all volunteer growth of whatever nature be completely killed out in the fields before seeding the following crop, and it is thought that if this be done such ravages as have occurred in the past can not be repeated.

Investigations seem to indicate that no noticeable good resulted from the introduction of the parasite *Aphidius testaceipes*. "When one stops to consider the numerous and varied hosts of *A. testaceipes*, its manner of hibernation, its wide distribution, and the higher temperature required for its development over and above that needed by its host; also the fact that it may readily be transported along with its host as adults, or within the body of the latter, one can readily see the futility of attempting materially to increase its numbers or efficiency by artificial introduction into grain fields."

Aphididæ of southern California, VIII, E. O. ESSIG (*Pomona Col. Jour. Ent.*, 4 (1912), No. 2, pp. 698-745, figs. 17).—This continuation of the author's studies (*E. S. R.*, 26, p. 149) includes descriptions of several new genera and species.

Woolly aphis, or American blight (*Schizoneura lanigera*), W. W. FROG-GATT (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 6, pp. 520-528).—This is a summarized account.

A contribution to the knowledge of the Phylloxerinae, B. GRASSI ET AL. (*Contributo alla Conoscenza delle Fillosserine ed in Particolare della Fillossera della Vite*. Rome, 1912, pp. X+456+LXXV, pls. 20, figs. 31).—The first part of this work (pp. 3-86) deals with studies of phylloxera other than that

of the vine; the second part (pp. 87-417) with studies of the grapevine phylloxera (*Phylloxera vastatrix*) with observations comparing it with other species. A bibliography of 13 pages follows.

A second paper, by Anna Foá (pp. I-LXXV), is devoted to the biology of the grapevine phylloxera.

**Natural control of white flies in Florida.** A. W. MORRILL and E. A. BACK (*U. S. Dept. Agr., Bur. Ent. Bul. 102, pp. 78, pls. 9, fig. 1*).—This is a detailed report of investigations commenced in 1906 and extending over a period of 4 years. The subject is taken up under the headings of parasitic and predatory enemies of white flies; snails that feed on sooty mold; climatic conditions; unexplained mortality; dropping from leaves; mortality due to overcrowding; effect of curling and dropping of leaves from drought; bacterial diseases; and fungus diseases.

"No true parasites of these species of white flies are known to exist in this country and their numerous native predatory enemies are usually of no material assistance in their control. Two factors of natural control, overcrowding and unexplained mortality, have heretofore not been recognized or have been confused with the results of attempts at artificial control or with the effects of fungus diseases. The 2 factors named are in effect a reaction from excessive infestation. Bacterial diseases of the white flies are at present unknown but it is not improbable that they are the leading cause of mortality so far unexplained. . . .

"Aside from unexplained mortality, fungus diseases are the most important agents of natural control. The brown fungus (*Aegerita webberi*) and the red Aschersonia (*Aschersonia atcyrodia*) are, in the order named, the most effective parasites of the citrus white fly. The yellow Aschersonia (*A. flavo-citrina*) is the most effective parasite of the cloudy-winged white fly. The cinnamon fungus (*Verticillium heterocladum*) and the Sporotrichum fungus (*Sporotrichum* sp.) are of comparatively little importance. The red-headed scale fungus (*Sphaerostilbe coccophila*) is rarely parasitic upon white flies, while the white fringe fungus (*Micococca* sp.) is with little doubt normally saprophytic. The fungus parasites thrive only under suitable weather conditions during a period of about 3 months each year, generally speaking the summer months in the case of the 2 Aschersonias and the fall months in the case of the brown fungus. Their efficacy in destroying white flies under natural conditions is dependent upon the abundance of the insects; a period of excessive abundance always precedes effective temporary control. . . . Under natural conditions, without artificial assistance in spreading, the fungi have ordinarily, in favored localities, controlled the white fly to the extent of about one-third of a complete remedy through a series of years. . . .

"The authors conclude that there are at present no elements of natural control herein dealt with which can be relied upon to give satisfactory results. Under present conditions it is unquestionably more profitable to depend upon artificial remedies."

**White fly parasites and their attempted introduction into Florida.** R. S. WOGLUM (*Fla. Grower, 6 (1912), Nos. 9, p. 3; 10, p. 3*).—An address on the attempted introduction of insect enemies of the white fly from India, a brief account of which by L. O. Howard has been previously noted (*E. S. R., 25, p. 661*).

**Some scale insects of Mississippi, with notes on certain species from Texas.** G. W. HERRICK (*Mississippi Sta. Tech. Bul. 2, pp. 3-78, figs. 96*).—This bulletin discusses the collection and preservation of scale insects, the literature, and the technique to be made use of in preparing them for study, and gives a list of 40 species known to occur in Mississippi, 6 additional from Texas, and 1 from

Louisiana. Technical descriptions and illustrations are presented of 35 of the species.

**Mites associated with the oyster-shell scale (*Lepidosaphes ulmi*).** H. E. EWING and R. L. WEBSTER (*Psyche*, 19 (1912), No. 4, pp. 121-134, fig. 1).—Observations made in Iowa in 1911 showed a great variation in the condition of the oyster-shell scale at different places in the State. In some of the infested orchards near Ames, as low as 3.7 per cent of the scales contained sound eggs in the spring of 1911, the remainder being either empty or gutted by mites. Samples of scale collected in an orchard at Northwood, near the Minnesota line, showed that from 23 to 82.4 per cent contained sound eggs. *Hemisarcoptes malus* is said to be the most important enemy of this scale.

Of a total of 9 species of mites found in connection with the oyster-shell scale 6 were either parasitic or predaceous. These 6 species, notes on which are here presented, are *H. malus*, *Tydeus coccophagus*, *Bdella cardinalis*, *Cyta brevipalpa*, *Anystis agilis*, and *Eupalus* sp.

**Studies of intracellular symbiosis.** P. BUCHNER (*Arch. Protistenk.*, 26 (1912), No. 1, pp. 116, pls. 12, figs. 29).—This first paper deals with the intracellular symbiosis of Hemiptera.

**Eri silk.** H. MAXWELL-LEFROY and C. C. GHOSH (*Mem. Dept. Agr. India, Ent. Ser.*, 4 (1912), No. 1, pp. 130, pls. 9, figs. 13).—This paper discusses rearing, diseases, influence of climate, treatment of cocoons, the castor plant, and the eri silk industry in India generally and in Assam.

**Orgyia leucostigma: A factor in the causation of Ophthalmia nodosa.** G. W. BEATTY (*Med. Rec. [N. Y.]*, 82 (1912), No. 8, p. 342, fig. 1).—The author reports cases in which the introduction of hairs from the caterpillars of the white-marked tussock moth produced a nodular condition of the conjunctivæ.

**The nun moth problem in Saxony.** C. F. C. BEESON (*Quart. Jour. Forestry*, 6 (1912), No. 3, pp. 188-194, pl. 1, fig. 1).—This is a discussion of the present status of the nun moth situation in Saxony.

**Papers on insects affecting vegetables.**—A report of progress regarding the sugar beet webworm (*Loxostege sticticalis*), H. O. MARSH (*U. S. Dept. Agr., Bur. Ent. Bul.* 109, pt. 6, pp. 57-70, figs. 15).—This is a preliminary report based upon observations made by the author during portions of the years 1909 and 1910, and nearly all of 1911, while engaged in investigations of the insects affecting sugar beets and truck crops in the Arkansas Valley of Colorado and Kansas. The injury caused by this pest has varied greatly from year to year.

The moths deposit their eggs singly or in rows of from 2 to 5 or more, usually on the underside of the leaf. Under normal conditions each female is capable of depositing at least 200 eggs. The very young larvæ eat small holes in the underside of the leaves without cutting through the upper epidermis, but as they increase in size they consume almost the entire leaf with the exception of the larger veins and the petioles. When full grown the caterpillars leave the beets and burrow into the soil, usually close about the infested plant, and spin tube-like cases in which they later pupate. During the summer months the moths issue within a few days.

“In rearing experiments conducted at Rocky Ford, Colo., the average time required from the deposition of the eggs until the moths issued was a little more than a month. The egg stage was observed to vary from 3 to 5 days, the larva stage from 17 to 20 days, and the pupa stage was usually 11 days. These variations were from records of successive generations. So far as the writer has been able to determine, there are 3 generations or ‘crops’ of webworms in the Arkansas Valley each year. There may be a fourth generation, but if so it is not clearly marked and possibly occurs early in the season on weeds such as Russian thistle (*Salsola tragus*) and lamb’s quarters (*Chenopodium*

album). . . . In general the danger period extends from shortly before the middle of June until well into September. The first generation of webworms may be expected at its height of destructiveness during the latter half of June, at a time when the beets are comparatively small and least able to resist the attack."

Blackbirds are said to be important enemies of this pest. True parasites in some cases destroy fully 50 per cent of the overwintered larvæ, the braconid *Diosphyrus vulgaris* being one of the most common. Spraying with Paris green at the rate of 3 lbs. to 100 gal. of water to which either 6 lbs. of whale-oil soap or 3 lbs. of lime have been added has proved to be by far the most effective and satisfactory remedy. Zinc arsenite, when used at the rate of 4 lbs. in 100 gal. of water and applied at the rate of 125 gal. per acre, was effective but was noticeably slower than Paris green in its killing effect. It is stated that the cost of labor, material, etc., for spraying sugar beets varied under ordinary circumstances from \$1 to \$2 per acre. The spraying machinery recommended for use in the work is described and illustrated.

The natural enemies of the cotton worm, L. H. GOUGH (*Agr. Jour. Egypt*, 2 (1912), No. 1, pp. 1-3, pl. 1).—*Calosoma imbricata*, which is parasitized to a very great extent during its larval stage by at least 2 parasitic flies; a Rover beetle (*Paderus* sp.); the gauze-wing fly (*Chrysopa vulgaris*); a solitary wasp (*Eumeces marillosa*); and *Polistes gallica* are the enemies of the Egyptian cotton worm (*Prodenia litura*) here considered and illustrated in colors.

Methods employed in Egypt and elsewhere to check the ravages of the cotton bollworm, G. C. DUDGEON (*Agr. Jour. Egypt*, 1 (1911), No. 1, pp. 40-46).—This paper relates to *Earias insulana*.

The control of the codling moth, A. L. MELANDER (*Washington Sta. Popular Bul.* 45, pp. 8, figs. 7).—A brief popular account.

Notes on Tineina bred from cotton bolls, J. H. DURRANT (*Bul. Ent. Research*, 3 (1912), No. 2, pp. 203-208, figs. 3).—These notes relate to the pink bollworm (*Getechia gossypiella*), *Pyroderces simplex*, and *P. rileyi*.

Lepidoptera heterocera; family Geometridæ, L. B. PROUT (*Genera Insectorum*, 1912, No. 129, pp. 274, pls 5, figs. 15).—The subfamily Hemitheinae is here dealt with.

New Culicidæ, F. V. THEOBALD (*Nova Culicidæ. Wye, England, 1911, pt. 1, pp. 35, figs. 21*).—This first part gives descriptions of Culicidæ from Uganda, 13 species being described as new to science.

The rôle of the house fly and certain other insects in the spread of human diseases, W. E. BRITTON (*Pop. Sci. Mo.*, 81 (1912), No. 1, pp. 36-49, figs. 5).—An address delivered by the author.

Fruit fly control, W. M. GIFFARD (*Hawaii. Forcster and Agr.*, 9 (1912), No. 5, pp. 166-170).—This paper adds *Chrysophyllum oliviforme* and *Thevetia nerifolia* to the long list of fruits or seeds infested by the Mediterranean fruit fly.

The petroleum fly in California (*Psilopa petrolei*), D. L. CRAWFORD (*Pomona Col. Jour. Ent.*, 4 (1912), No. 2, pp. 687-697, fig. 1).—A discussion of the habits of this insect and of the structure of the larva.

Blood-sucking Diptera in Venezuela, J. M. R. SURCOUF and R. GONZALEZ-RINCONES (*Essai sur les Diptères Vulnérants du Venezuela. Paris, 1911, pt. 1, pp. V+320, figs. 65*).—This first part of the work deals with the blood-sucking Nematocera.

Blood-sucking Diptera actually known from Venezuela, J. SURCOUF and R. GONZALEZ-RINCONES (*Arch. Par.*, 15 (1912), No. 2, pp. 248-314, figs. 43).—This paper relates to the studies noted above.

The Siphonoptera of Lima and Callao, E. D. TOVAR Y R (*Bol. Div. Fomento [Peru]*, 9 (1911), No. 11, pp. 16-37).—This is a general discussion of the fleas which occur in Peru.

The injurious buprestids, F. PICARD (*Prog. Agr. et Vit. (Ed. l'Est Centre)*, 33 (1912), No. 31, pp. 133-139, pl. 1).—Short accounts are given of 6 of the more important buprestids occurring in France, namely, *Sphanoptera gemellata*, *Corymbus bifasciatus*, *C. undatus*, *Chalcophora mariana*, *Capnodis tenebrionis*, and *Ptosima noveboracensis*.

The bark-eating and root-boring beetles (*Coelosterna scabrata* and *Psiloptera fastuosa*) of the babul (*Acacia arabica*), E. P. STEBBING ([*Indiuu*] *Forest Bul.* 12, 1912, pp. 9, pls. 2).—Considerable injury in babul plantations in Berar has been due to the attacks of these longicorn and buprestid beetles.

Coleoptera; family Curculionidæ, H. WAGNER (*Genera Insectorum*, 1912, No. 130, pp. 109, pls. 6).—This fascicle takes up the subfamily Apioninæ. A plate showing the distribution of the genera is included.

The plum curculio, A. L. QUAINANCE and E. L. JENNE (*U. S. Dept. Agr., Bur. Ent. Bul.* 103, pp. 250, pls. 20, figs. 36).—This bulletin gives the results of studies that have been in progress since the spring of 1905. Data have been obtained on the biology of the insect in northern, central, and southern localities in its range of distribution, as in western New York and northwestern Pennsylvania, in the environs of Washington, D. C., and in Georgia. Studies for one season were made in the Ozark region of Arkansas, well toward its limit of occurrence to the Southwest.

The subject is taken up under the headings of classification and synonymy, common names, history, distribution, losses due to the plum curculio, insects likely to be mistaken for it, its description, food plants, life history and habits, seasonal history, percentage of fruit punctured or infested, natural enemies, and remedial measures.

The curculio is indigenous to the eastern United States, and has probably always occupied about its present range of distribution. Investigations conducted show this pest to occur in the humid area in all of the life zones, except the tropical, it having been found as far west as Sterling, Colo. (long. 103°). The authors estimate the annual loss, including cost of remedial operations, resulting from the attack of the curculio, at about \$8,500,000.

The plum curculio feeds upon and oviposits in practically all pome and stone fruits, as the apple, pear, quince, plum, peach, cherry, nectarine, and apricot. Certain wild fruits, such as *Cratægus*, crab apple, etc., are also more or less fed upon, especially when the above mentioned fruits are scarce. There are also records of oviposition in the huckleberry, grape, strawberry, gooseberry, currant, and wild persimmon. It also breeds in black knot.

In comparing the number of eggs deposited by different individuals for the respective localities and the averages of all beetles for a given locality, the authors find a great variation. The final average number of eggs per female for all localities is 144.85, ranging from 1 to 557 eggs. The length of the egg stage ranges from 2½ to 13½ days for the different localities, the averages varying from 3.77 to 9.23 days.

In observations made in Michigan in 1910, the length of the 4 larval instars was 2, 2.4, 2.7, and 4.1 days, respectively. Comparatively few beetles emerge from the soil within 3 weeks from the time of entering as larvæ. The great majority of the beetles appear during the fourth and fifth weeks and by the close of the sixth week emergence has practically ceased. At Barnesville, Ga., the average number of days for the larvæ in the soil before pupation was 16.08 as against 12.03 in Michigan. In Georgia the average time spent by the adults in the ground before emerging was 5.62 days. The average time 37 individuals spent in the soil was 30.89 days. Of a total of 1,083 larvæ, 684 pupated within 1 in. of the surface, and 1,019 within 2 in. of the surface. The several averages of time for complete transformations in the individual records show a range of

from 36.97 to 67.23 days, the former from the insectary records of 1905 at Washington and the latter from Barnesville, Ga., in 1910.

The records indicate that the curculio feeds rather more at night than in the day and that egg laying goes on at about an equal rate during night and day. "It appears that the curculios usually first appear on the trees each season at nearly the same time relative to the advancement of fruit trees, namely, during or a little before the blooming period of apples or shortly after the petals of peaches, pears, and plums have fallen. In some seasons, however, the curculios may appear as early as the blooming period of the plum or be retarded until after apples have shed the petals. Thus it appears that the beetles are affected by temperature to a different degree than are the plants on which they live." A second generation is said to have been reared to the adult stage at Barnesville, Ga., in 1910.

The plum curculio is said to be attacked by several species of parasites, among which the authors consider *Anaphoidea conotracheli*, which parasitizes the eggs, and *Triaspis curculionis*, *T. curculionis rufus*, *Thersilochus conotracheli*, *Microbracon mellitor*, *Myiophasia auca*, *Cholomyia inaequipes*, and *Pegomya fusciceps*. In discussing remedial measures a historical account of the earlier methods first given is followed by a consideration of the relative value of collecting, spraying, and cultivation for the destruction of the pupæ.

"Considering the several records of jarring on peach given above, it would appear that this practice, on the whole, is not warranted from the benefits derived. Notwithstanding the large total of beetles caught in the course of the Barnesville experiment, averaging 20.81 per tree, there was a lessening of infestation of only about 10 per cent, as compared with the check. . . .

"The records given of results of spraying apples for the control of the curculio indicate clearly that the injuries of the pest may be in all cases greatly reduced, although the degree of benefit varies widely. It is apparent that account must be taken of other factors, as the relative abundance of the insects as compared with the amount of fruit present on the trees. With a small fruit crop and abundance of curculios, the most thorough spraying will not serve to bring through a satisfactory amount of sound fruit. . . . The degree of success in spraying varies with the abundance of the insects, and where the latter are numerous thorough treatments seem to fail to yield a desired freedom from injury." A schedule consisting of 4 sprayings is recommended for apple orchards and should control the plum curculio as well as numerous other insect enemies.

A combination of arsenate of lead and self-boiled lime-sulphur wash, while resulting in important chemical changes, has in actual practice resulted in a spray which appears to be perfectly safe to peach foliage and fruit. Experience during the past 3 years with this combined spray on peaches under varying climatic conditions seems to leave no doubt that by this combination the injurious properties of the arsenate of lead, as when used alone, are so reduced as to be practically negligible. "More data are needed to show the protection from curculio which will follow spraying plums and cherries, though this will without doubt be quite as marked as with peaches. The same spraying schedule indicated for early peaches will be suitable for plums and cherries, and the arsenical should be used in the self-boiled lime-sulphur wash."

A bibliography of economic literature consisting of 23 pages is appended.

Texas bee keeping, L. H. SCHOLL (*Tex. Dept. Agr. Bul. 24, 1912, pp. 142, figs. 115*).—This bulletin has been prepared by an experienced bee keeper to meet the requirements of those who desire complete practical instructions concerning bee keeping.

**Comb honey.** G. S. DEMUTH (*U. S. Dept. Agr., Farmers' Bul. 503, pp. 47, figs. 20*).—This bulletin presents an analysis of the best practice and points out some essentials to the production of maximum crops of honey of the best grades.

The subject is taken up under the headings of apparatus for comb-honey production, manipulation of the bees, and caring for the crop.

**A successful queen-cage candy made without honey,** A. C. MILLER (*La. Planter, 49 (1912), No. 11, p. 185*).—A candy which contains no honey has been prepared for use in queen cages from the following constituents: Granulated sugar, 5 lbs.; coffee A sugar, 1 lb.; glucose, 1 lb.; water, 1½ pt.; and 1 level teaspoonful of cream tartar. After mixing, the ingredients are boiled without stirring until the temperature reaches 240° F. for summer use, or 232° for winter use, then removed from the fire, stirred until thickened, and run into molds, feeders, or cages.

It is stated that queens have been successfully shipped to England and that full colonies shaken from their combs have been shipped with no other food than this candy with the best of results.

**South African "fertile-worker bees,"** G. W. ONIONS (*Agr. Jour. Union So. Africa, 3 (1912), No. 5, pp. 729-728*).—This is a report of personal observations.

**South African fertile-worker bees and parthenogenesis,** D. S. VAN WARMLEO (*Agr. Jour. Union So. Africa, 3 (1912), No. 6, pp. 786-789*).—This is a critical review of the article noted above.

**Wild honey: With notes on the Moka bee,** E. N. MARAIS (*Agr. Jour. Union So. Africa, 3 (1912), No. 6, pp. 790-795*).—In an appended note by C. B. Hardenberg it is stated that the species here considered, namely, the larger Moka bee, is closely allied to, if not identical with, *Trigona clypeata*.

**A new encyrtid (Encyrtus sericophilus) beneficial to sericulture,** A. CONTE (*Compt. Rend. Acad. Sci. [Paris], 154 (1912), No. 18, pp. 1182, 1183*).—The encyrtid here described as new to science parasitized the greater number of the pupæ of a tachinid parasite (*Tricholyga sorbillans*) of the silkworm received by the author from Tan Chau, Indo-China.

**The life history and bionomics of some North American ticks,** W. A. HOOKER, F. C. BISHOPP, and H. P. WOOD (*U. S. Dept. Agr., Bur. Ent. Bul. 106, pp. 239, pls. 15, figs. 17*).—This is a report of studies conducted in large part in the field laboratory of the Bureau of Entomology at Dallas, Tex., from 1907 to 1910. The first part of the bulletin is devoted to an account of ticks in general, including systematic position and classification; collecting, preserving, and mounting; economic importance; history of the biological study of ticks; geographical distribution; general life history; habits; multiplication; locomotion and dissemination; seasonal history; methods employed in studies of ticks; natural control; and artificial control.

The life history and bionomics of 19 forms are considered. Under each species the authors present a description of the size and coloration of the various stages, their host relationship, geographical distribution, observations of the length of the various stages, number of eggs deposited, etc., based upon temperature readings, a summarized account of the life cycle, economic importance, and natural and artificial control. The species and varieties thus considered are the fowl tick (*Argas miniatus*), spinose ear tick (*Ornithodoros mcgini*), black-legged tick (*Ixodes scapularis*), rotund tick (*I. kingi*), rabbit tick (*Hæmaphysalis leporis-palustris*), bird tick (*H. chordeilis*), brown dog tick (*Rhipicephalus sanguineus*), North American cattle tick (*Margaropus annulatus*), Australian cattle tick (*M. annulatus australis*), gopher-tortoise tick (*Amblyomma tuberculatum*), iguana tick (*A. dissimile*), Gulf Coast tick

(*A. maculatum*), lone star tick (*A. americanum*), cayenne tick (*A. cajennense*), rabbit Dermacentor (*Dermacentor parumapertus marginatus*), Rocky Mountain spotted-fever tick (*D. venustus*), Pacific Coast tick (*D. occidentalis*), American dog tick (*D. variabilis*), and tropical horse tick (*D. nitens*).

A list of bibliographical references is appended.

**Rocky Mountain spotted fever**, W. C. RUCKER (*Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Rpts., 27 (1912), No. 36, pp. 1465-1482*).—This summarized account includes a bibliography of 77 titles.

**The origin and significance of parasitism in the Acarina**, H. E. EWING (*Trans. Acad. Sci. St. Louis, 21 (1912), No. 1, pp. 70, pls. 8*).—"We have very strong evidence indicating that the parasitic habit has originated independently at least 11 times in the phylogeny of the Acarina. Among the zoophagous parasites the parasitic habit has been developed from 3 different types of free living Acarina: (a) Predaceous forms, (b) scavengers, (c) forms living upon the juices of plants. . . . As is usually the case with other parasites, we generally find here a gradual increase in the state of degeneration as we follow the advancing stages of parasitism from its origin among free types. . . . We find in the Acarina a process of degeneration which in its completeness is seldom obtained in the animal kingdom."

### FOODS—HUMAN NUTRITION.

**Sewage-polluted oysters as a cause of typhoid and other gastro-intestinal disturbances—a study of an epidemic and of certain individual cases**, G. W. STILES (*U. S. Dept. Agr., Bur. Chem. Bul. 156, pp. 44, pls. 4, figs. 7*).—According to the author's conclusions from his investigations and a summary of data, "there is undisputed evidence to show that infected oysters, clams, mussels, scallops, and other shellfish may cause typhoid fever and other gastro-intestinal disturbances when consumed by susceptible individuals.

"The epidemics of typhoid fever, due to ingestion of polluted sea food, have in most instances been traced to shellfish floated in polluted water, although there is also evidence that oysters and other shellfish, grown in polluted waters and directly consumed without transplanting for a time in pure waters, may be the source of typhoid infection."

A full account is given of investigations which led to the conclusion that Rockaway oysters were wholly responsible for cases of typhoid fever and gastro-enteritis (diarrhea) following a banquet. There were 17 well-defined cases of typhoid fever, with 1 death, and 83 cases of gastro-enteritis traced directly to such oysters from Jamaica Bay, floated at Indian Creek, near Canarsie, Long Island, N. Y., with 10 additional cases of typhoid and 16 cases of diarrhea traced to oysters from the same locality and in part from the same lot as those furnished for the banquet.

"This investigation comprises a complete study of all the factors which would materially contribute to typhoid infection. Each item of the menu served at the . . . banquet was carefully considered, and the Rockaway oysters served were the only articles of food consumed by all of those who had typhoid or gastro-enteritis following this banquet."

Bacteriological studies showed sewage pollution in Jamaica Bay, and "typhoid bacilli were isolated in pure culture after 7 and 21 days from oysters which had been floated at Inwood, Long Island, N. Y., . . . and kept out of water in storage at 39° F. Organisms of the *Bacillus coli* and *B. paratyphosus* groups were also isolated from oysters floated at Indian Creek. . . . They were probably the cause of the gastro-enteritis cases following the . . . banquet."

The diarrhea or bowel trouble referred to, according to the author's conclusions, can probably be ascribed to the presence of paratyphoid bacilli (said by

some authors to be indistinguishable from or closely allied to the Gaertner bacillus) in the oysters served at the banquet. "It is apparent that the disease was due to bacterial infection, arising from the multiplication of the organisms in the body after ingestion, and not to 'ptomaines,' as suggested by some.

"Ptomaines are formed most commonly during the decay of animal matter. They are essentially the decomposed animal tissue, not excretions of the bacteria, although the bacteria are responsible for the decomposition. Such decomposition does not occur usually in the body, even in animal matter taken as food. In abnormal conditions, if food remains in the body until putrefied, ptomaines may be formed in the intestinal contents. When decomposed food containing ptomaines is received in the digestive tract, or originally good food decomposes there, the mucous membrane and blood may take up ptomaines from this decomposed food, which ptomaines affect the tissues like other poisons.

"Substances of quite varied chemical constitution are classed under the head of ptomaines solely on account of their origin in proteid decomposed by bacterial action. Bacterial toxins are to be distinguished from ptomaines. Toxins are substances which are or have been a part of the body of the bacteria; some are secretions from the germ, others are liberated only in case of the death and breaking down of the germ itself. In this latter class is the toxin of typhoid fever, which is therefore particularly different in its origin and action from ptomaines. The toxins are much more poisonous than ptomaines and each one is produced by a specific germ.

"Some cases of sickness due to food have been classed as ptomaine poisoning, when this cause was later discovered to be the ingestion in the food of a particular bacillus which multiplied in the body and by its toxin produced intestinal and other disturbances. Such cases are not ptomaine poisoning but may be classed as food poisoning."

**Studies of meat corned by the Morgan process, K. VON KARAFFA-KORBUTT** (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 24 (1912), No. 6, pp. 365-385).—From an experimental study of this method of pickling meat and a summary of published data, general conclusions were drawn including, among others, the following:

The method of pickling the meat is not less important than its further treatment. Ripening should take place in rooms with a temperature of about 0° C. It requires from 4 to 6 weeks in order that the osmotic processes may be completed and the meat be uniformly salted. Storing corned meat for a sufficient time at a low temperature improves its keeping quality. The relation between the temperature of storerooms and the spoiling of pickled meat lies in the symbiosis of different bacteria which gain access to it. Low temperature favors the development of yeast forms and acidophylic bacteria and lessens the growth of septic bacteria, and it is therefore a favorable factor in keeping quality.

**On the falsification of the rice, S. SATO** (*Yakugakuzasshi (Jour. Pharm. Soc. Japan)*, 1912, No. 361, pp. 217-241, figs. 3).—It is stated that fine gravel and siliceous earth are added to rice as an adulterant as well as to assist in removing the hulls. The percentage of ash in such cases may be as high as 6.36 per cent, while good rice should have less than 1 per cent of ash.

**The milling quality of Washington wheats, III, R. W. THATCHER** (*Washington Sta. Popular Bul.* 39, pp. 8).—A summary of data previously noted (*E. S. R.* 25, p. 857).

**How to make bread from soft wheat flours, G. A. OLSON** (*Washington Sta. Popular Bul.* 47, pp. 4, fig. 1).—Directions are given for preparing yeast and for mixing and handling the dough from Washington soft wheat flours.

The author insists that ingredients should be weighed. Directions are given for determining the amount of water required by different flours, and some data presented showing the influence of water and kneading on the size and texture of the loaf. According to the data presented, there is always an increase in the weight of bread and volume of loaf with a reasonable increase of water used in mixing the dough, while at the same time there is a reduction in the time required for fermentation and baking. When straight doughs are compared with those involving kneading "it is observed that the weight of the loaf is practically the same in all cases when like amounts of water were used. The largest weights were obtained where the flour was kneaded the second time." The smallest volume was obtained in the case of straight dough where the minimum amount of water (52.5 per cent) was used and the largest volume in the case of lightly handled dough with a second kneading where 65.5 per cent of water was used.

Bulgarian bread, a little known dough fermentation (*Pure Products*, 8 (1912), No. 7, pp. 384, 385).—The bread here described is made of fine wheat flour and leavened by the activity of a bacillus of the Coli group, called *B. macedonicus*. The bread is said to have a pleasant taste and a fine, fruity aroma.

Concerning the physiological effect of chicory infusion, J. PAECHTNER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 6, pp. 241-250, *dgms.* 6).—From experiments with a rabbit and dogs the author concludes that chicory exercises a noticeable though not very great stimulating effect upon the digestive apparatus and the circulation of the blood, and that this rather than the taste explains the general use of this material as a food accessory. He does not believe that under normal conditions there is any reason for considering chicory harmful.

Food inspection decision (*U. S. Dept. Agr., Food Insp. Decision* 148, pp. 2).—The use of copper salts in the greening of foods is declared an adulteration under the Food and Drugs Act after January 1, 1913.

Sulphite in sugar goods, H. WITTE (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 24 (1912), No. 7, pp. 463-465).—The occurrence of sulphurous acid in candies is reported and discussed.

The art of good living, E. RICHARDIN (*L'Art du Bien Manger. Paris, 1910*, pp. XVI+a+926, pls. 51, figs. 51).—In this volume, which bears the subtitle French Cookery from the Fourteenth to the Twentieth Century, a large amount of historical and general data regarding food and its preparation is summarized and many recipes are included.

Good living (*Pour Bien Manger. Paris, 1912*, pp. XXXII+340, pls. 24, figs. 43).—This volume discusses at length cooking schools, kitchen equipment, service, and other matters of housekeeping, and gives a large number of recipes for preparing different foods. Data are also summarized regarding the adulteration of food.

Beriberi caused by fine white flour, J. M. LITTLE (*Jour. Amer. Med. Assoc.*, 58 (1912), No. 26, pp. 2029, 2030).—A diet consisting almost exclusively of fine white flour, tea, and molasses, made necessary by shortage of food supplies in Newfoundland and Labrador, resulted in beriberi, according to the author's experience.

Substitution of whole wheat flour is recommended. He believes that the more the diet is restricted to flour, the more necessary it is to have whole wheat flour.

Preparation from yeast and certain foodstuffs of the substance the deficiency of which in diet occasions polyneuritis in birds, C. FUNK (*Jour. Physiol.*, 45 (1912), No. 1-2, pp. 75-84; *abs. Jour. Chem. Soc. [London]*, 102

(1912), No. 599, II, p. 856).—A substance which appears to be a pyrimidin base, forming a constituent of nucleic acid, was isolated from yeast, milk, brain, and possibly lime juice. From 0.02 to 0.04 gm. in food prevented polyneuritis in pigeons.

**The influence of meal hours upon energy elimination in man, J. AMAR** (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 8, pp. 528-531; *Jour. Physiol. et Path. Gén.*, 14 (1912), No. 2, pp. 298-308; *abs. in Zentbl. Expt. Med.*, 1 (1912), No. 14, pp. 634, 635; *Zentbl. Physiol.*, 26 (1912), No. 7, pp. 351, 352).—In these experiments the effect on the respiratory quotient and oxygen consumption of carbohydrate as compared with nitrogenous food, and of a constant amount of work performed at different intervals after ingestion of food was noted.

The author concludes that the performance of a given amount of work is 4.5 per cent more difficult and that the energy is available much more slowly on a nitrogenous than on a carbohydrate diet.

**The influence of dry and moist air on gaseous metabolism, H. MURSCHEHAUSER and H. HIDDING** (*Biochem. Ztschr.*, 42 (1912), No. 5, pp. 357-371; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 599, II, p. 850).—Experiments were made to determine the effect of humidity on gaseous metabolism, using guinea pigs.

At 5° C. there was 76.5 per cent more of carbon dioxide in dry air, and 82.8 per cent more in moist air, than at 21°. There was 18.7 per cent less carbon dioxide in dry air, and 7.1 per cent more in moist air, at 35° than at 21°. Carbon dioxide metabolism at 21° is greater in dry than in moist air.

The author's explanation of the observed facts is that the lower the temperature, the greater the degree of saturation with water vapor, and consequently the less the loss of body heat. Increase of moisture diminishes carbon dioxide production, while decrease of moisture has the opposite effect. At higher temperatures, increase in moisture content up to the point of saturation is associated with increased body temperature, indicating increased metabolism. The results in relation to size of body surface are discussed.

## ANIMAL PRODUCTION.

**The nature, origin, and maintenance of life, E. A. SHÄFER** (*Nature [London]*, 90 (1912), No. 2236, pp. 7-19; *Sci. Amer. Sup.*, 74 (1912), Nos. 1918, pp. 221-223; 1919, pp. 226, 227; 1920, pp. 254, 255).—This is the inaugural address of the president of the British Association for the Advancement of Science, 1912, and discusses the fundamental principles governing the origin, growth, and maintenance of animals and plants as revealed by physical, chemical, and biological studies.

**The process of reproduction in organisms, C. M. CHILD** (*Biol. Bul. Mar. Biol. Lab. Woods Hole*, 23 (1912), No. 1, pp. 1-39).—A discussion of the reproductive power of both somatic and germ cells.

It is stated that the experimental data of recent years do not support the germ plasm hypothesis of Weismann. The view is also expressed that our theories of heredity, instead of being based solely on the phenomena of sexual reproduction, must find their basis for analysis and interpretation in the simpler forms of asexual and experimental reproduction. Heredity is defined as the capacity of the physiologically or physically isolated part for regulation.

**The interstitial cells and the supposed internal secretion of the chicken testis, ALICE M. BORING** (*Biol. Bul. Mar. Biol. Lab. Woods Hole*, 23 (1912), No. 3, pp. 141-153, figs. 9).—The object of this work was to find evidence of the reproductive organs as a cause for the development of secondary characters,

the male fowl being an especially good animal because of the extensive development of the characters to be studied.

The histological studies revealed no cells in the interstitial tissue in the young or old chicken testis with the cell bodies differentiated from the connective tissue fibers. The differences in shape depended on the mechanical pressure conditions. The difference in staining capacity of the nuclei was not considered a basis for cell classification. The fat in the testis was thought to be brought there by the circulation and deposited, instead of being formed by the interstitial tissue. No evidence was found in this study which would indicate an internal secretion of any kind formed by interstitial tissue. Therefore, it is concluded that there is no interstitial cell in the testis of the domestic chicken in the sense that the term has been previously used.

The iron content of the urine of domesticated animals, M. REICH (*Das Harncisen der Haustiere. Inaug. Diss., Univ. Rostock, 1911, pp. 41; rev. in Zentbl. Agr. Chem., 41 (1912), No. 4, pp. 272-275*).—In normal feeding the amount of iron excreted per kilogram of urine was as follows: Dogs from 1.1 to 1.42, swine from 1.3 to 1.58, oxen 0.918, goats 0.498, horses from 0.51 to 0.83, and sheep from 0.73 to 1.34 mg. The amount excreted per day for animals was as follows: Dog 0.33, swine 5, oxen 12.55, goats 0.5, and sheep 1 mg. As in the case of man the iron was in inorganic compounds.

The discordant results of many investigators is thought to be due to imperfect methods of determination. The author used a modification of the methods of O. Walter and H. Neumann.

Department of experimental evolution, C. B. DAVENPORT (*Carnegie Inst. Washington Year Book, 10 (1911), pp. 78-87, pl. 1*).—A report of progress made on problems in heredity, evolution, and genetics, including work on the following topics: Heredity in poultry, inheritance of double horn in sheep, reciprocal crosses in relation to sex, theory of pure lines, quantitative studies of selective elimination, influence of becoming feral on the development of the nervous system of the domestic animal, and the relation between heredity and the chemical action of pigment.

The problem of the improvement of domesticated species, H. BOULARD (*Bul. Écon. Indo-Chine, n. ser., 15 (1912), No. 97, pp. 479-491*).—A discussion of methods of selecting breeding animals, and brief notes concerning the ancestry of cattle.

Production of pure homozygotic organisms from heterozygotes by self-fertilization, H. S. JENNINGS (*Amer. Nat., 46 (1912), No. 548, pp. 487-491*).—The author illustrates with mathematical formulas how organisms may become homozygotes when self-fertilized for many generations, if the number of separable inheritable characters is not large.

The formation of condensed correlation tables when the number of combinations is large, J. A. HARRIS (*Amer. Nat., 46 (1912), No. 548, pp. 477-486*).—The author's aim in this article is to show how, in the case of relationships involving a very large number of combinations, the chief advantages of the correlation, but not the contingency, surface may be even more easily realized than in the method already described (*E. S. R., 25, p. 771*). Illustrations are given of this rapid method of carrying out the routine of a widely applicable statistical process.

Concerning a specimen of *Bos primigenius*, J. FELIX (*Sitzber. Naturf. Gesell. Leipzig, 37 (1910), pp. 35-38, pl. 1*).—This contains a description of measurements of a perfect skull of *B. primigenius*.

Progress in breeding in the State of Sao Paulo, Brazil, L. MISSON (*Ann. Gembloux, 22 (1912), No. 8, pp. 458-508, pls. 24*).—A general account of the

live-stock industry of Sao Paulo. Methods of feeding, breeding, and management are described, and a list of the principal forage plants and their yields per acre is also given.

**Live-stock industry [of southern India],** J. DE OLIVARES (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 241, pp. 211, 212).—This contains some statistics on the rapid development of the live-stock industry in southern India. This is attributed to various causes, chief of which are the greatly increased feeding resources resulting from extensive irrigation and the successful work of veterinarians in checking diseases to which cattle are subject.

**Managing and equipping a two-hundred-acre stock farm,** M. P. JARNAGIN (*Conn. Agr.*, 1 (1912), No. 4, pp. 147-161, figs. 10).—A system of live-stock farming is outlined, which includes data as to the amount of feed required for farm animals, the rotation of crops, and other points relating to the successful management of a live-stock farm.

**Our knowledge of the carbohydrates in the economy of the animal,** R. LÉPINE (*Rev. Gén. Sci.*, 23 (1912), No. 12, pp. 463-468).—This is a historical résumé of the growth of the knowledge on carbohydrate metabolism.

**The effect of sugar on metabolism,** A. GOUIN and R. ANDOUARD (*Compt. Rend. Soc. Biol.* [Paris], 72 (1912), No. 26, pp. 113-115).—An experiment with a 1½-year-old heifer, which lasted for 7 weeks. During the whole period the daily ration consisted of 800 gm. of peanut cake and hay ad libitum, and, in addition, during the first 3 weeks, potatoes; during the next 2 weeks one-half of the potatoes was replaced with carob beans; and during the last 2 weeks carob beans equal in nutrients to the potatoes fed at first. During the second period the potatoes and carob beans furnished 128 gm. saccharose daily, and during the third period the carob beans furnished 218 gm. saccharose daily.

There was a great reduction in the secretion of urine and urinary nitrogen and in general in the percentage of nutrients digested on addition of saccharose to the rations. The daily increase in weight was for the first period 501 gm., for the second period 1,000 gm., and for the third period 857 gm. The experiment will be repeated with a younger animal.

**Investigations on the meadow conditions of German Southwest Africa,** W. HEERING and C. GRIMME (*Arb. Deut. Landw. Gesell.*, 1911, No. 197, pp. 143).—A study of the soil types and geographical distribution of grasses and forage plants. Analyses and digestion coefficients of the following species are reported: *Aristida uniplumis*, *A. congesta*, *A. stipiformis*, *A. namaquensis*, *Cyathula hererænsis*, *Crotalaria diversistipula*, *Tribulus terrestris*, *T. incrimis*, *T. pechuelii*, *Andropogon contortus*, *A. papillosus*, *Panicum trichopus*, *Sporobolus indicus*, *S. nebulosus*, *Eragrostis trichophora* var., *E. porosa*, *E. laxissima*, *Cynodon dactylon*, *Anthephora hochstetteri*, *Fingerhuthia africana*, *Asparagus* sp., *Boerhavia pentandra*, *Albizzia anthelmintica*, *Acacia hebecada*, *A. hererænsis*, *A. giraffe*, *Rhynchosia gibba*, *Peltophorum africanum*, *Commiphora africana*, *Croton gratissimus*, *Flueggea aborata*, *Heeria mucronata*, *Rhus ciliata*, *R. albomarginata*, *Helinus oatus*, *Grevia bicolor*, *G. olukonde*, *Combretum hereræense*, *C. primigenium*, *Royena pallens* (?), *Ehretia hottentotica*, *Bouchea pinnatifida*, *Solanum incanum*, *Petalidium physaloides*, *Blepharis edulis* (?), *Cucumis prophetarum* var., *Tarchonanthus camphoratus*, *Dicoma anomala*, *Nidorclia auriculata*, *Cyperus usitatus*, *Citrullus vulgaris*, *Citrullus* sp., *Schmidtia pappophoroides*, *Poponarthria tuberculata*, *Lencosphæra bainesii*, *Hermstædtia dammarensis*, *Cleome rubella*, *Polanisia lüderitziana*, *Lotononis* sp., *Tephrosia purpurea*, *Rhigozum trichotomum*, *Catophractes alexandri*, *Pappophorum cenchroides*, *P. scabrum*, *Salsola aphylla* (?), *Zygophyllum affine microcarpum*, *Aitonia capensis*, *Leucas pechuelii*, *Setaria verticillata*, *Chloris*

*virgata*, *Atriplex vesicaria*, *Kochia salsoloides* (?), *Anisostigma schenckii*, and *Tamarix usneoides*.

The common names of these plants are given in German.

**Report of the animal husbandman, E. G. RITZMAN** (*Porto Rico Sta. Rpt. 1911, pp. 40-44*).—This contains a brief account of zebu crosses, African woolless sheep, and other station work in relation to animal husbandry.

Three years' investigation indicates that good silage can be made, and that native stock as well as the imported animals will eat it readily. Corn, whole cane, cane tops, and malojilla or Para grass have all given satisfactory results when fed as silage. Para grass when put in the silo was so light that it did not make good silage unless heavily ballasted. Six ft. of cut corn silage made a satisfactory ballast.

It was found that calcium chlorid could be used profitably as a supplement to bone meal in rations deficient in calcium. Middlings, shorts, and other mill feeds poor in calcium were too high in magnesium, and this excess of magnesium retarded assimilation and increased the cost of growth unless the effect was neutralized by calcium. Comparisons of calcium chlorid with tricalcium phosphate (bone meal) showed that there was only a small variation among individual pigs in utilization of calcium chlorid whereas there was a wide difference among individual pigs as regards utilization of bone meal.

**Silos and silage, R. C. ASNEY** (*Washington Sta. Popular Bul. 46, pp. 4*).—This discusses the advantages of including silage in the ration for live stock, and gives estimates on the cost of raising silage crops and building silos.

**Feeding stuffs inspection for 1912, B. E. CURRY and T. O. SMITH** (*New Hampshire Sta. Bul. 158, pp. 30*).—This contains the results of the annual feeding stuffs inspection, including analyses of 267 samples of cotton-seed meal, linseed meal, beef scraps, bone meal, cob meal, shredded wheat waste, corn-oil meal, buckwheat middlings, distillers' dried grains, malt sprouts, dried beet pulp, rye grains, gluten feed, hominy feed, wheat bran, wheat middlings, alfalfa meal, and proprietary mixed feeds. A discussion showing the expensive nature of low-grade feeds is also given.

**Feeding stuffs, F. MACI** (*Ber. Grossh. Bad. Landw. Vers. Anst. Augustenb., 1911, pp. 18-32*).—Analyses are reported of peanut cake, coconut cake, linseed cake, maize-oil cake, poppy cake, palm-nut cake, rape cake, sesame cake, soy-bean cake, wheat bran, wheat germ, distillers' slop, maize, fresh unshelled acorns, dried shelled acorns, dried sugar beet leaves, meat meal, fish meal, potato flakes, sugar-beet flakes, and apple pomace.

**The microscopic identification of cattle foods, G. H. CHAPMAN** (*Massachusetts Sta. Bul. 141, pp. 4-71, figs. 52*).—This bulletin contains brief descriptions of the characteristics of grains and grain products, legumes and oil seeds, weed seeds, and miscellaneous products, condiments, chemicals, and miscellaneous substances commonly found in commercial feeding stuffs, so that the ingredients can be easily identified by means of the microscope.

The text is accompanied by figures showing microscopic sections of cells, starch grains, etc. An analytical key to some commonly occurring starches is included.

**Corn silage and roots for steers, J. W. WILSON** (*South Dakota Sta. Bul. 137, pp. 354-367, figs. 11*).—This bulletin gives the results of 2 experiments in feeding corn silage to steers.

In the first experiment 20 yearling steers were divided into 5 lots of 4 each and fed for 90 days in order to test silage as a sole ration for wintering steers, as follows: Lot 1, silage from green corn cut when in the dent stage; lot 2, one-half as much silage as was consumed by lot 1 and all the hay they would eat; lot 3, silage from corn fodder cut at the same time as for lot 1 but put

into silo 10 weeks after it was cut; lot 4, millet hay cut when green and before seed matured; and lot 5, corn fodder from the field.

In the second experiment 24 yearling steers were divided into 6 lots of 4 each and fed for 120 days corn and oil meal 10:1, as a basal ration, and in addition the following: Lot 6, silage; lot 7, one-half as much silage as lot 1 and what hay they would eat; lot 8, sugar beets and hay; lot 9, mangel wurzel beets and hay; lot 10, stock beets and hay; and lot 11, hay.

The following table gives the comparative gains made in these tests:

*Comparative gains of yearling steers on silage with and without supplements.*

Experiment 1.			Experiment 2.			
Lot.	Average weight at beginning.	Average daily gain per head.	Lot.	Average weight at beginning.	Average daily gain per head.	Pork produced following steers.
	<i>Lbs.</i>	<i>Lbs.</i>		<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>

Experiments on the feeding of cattle, C. B. JONES (*Univ. Col. Wales, Agr. Dept. Bul. 1* [1912], pp. 1-12).—In an experiment with 12 Hereford and 8 Welsh Black 3-year-old cattle for 16 weeks the average daily gain per head for the lot fed 6 lbs. cotton-seed cake and barley meal daily was 1.55 lbs. against 1.6 lbs. for the lot fed 3½ lbs. of the same concentrates daily, the supplementary feeds in each case being straw, hay, and 50 lbs. of roots. In another experiment, in which the cattle were fed rations similar to the last-mentioned lot for 16 weeks, those allowed free access to water gained 1.92 lbs. each daily against 0.87 lbs. for those receiving no water except that contained in the feed.

Loss in weight of fattened cattle, HERTER and WILSDORF (*Arch. Deut. Landw. Gesell., 1911, No. 182, pp. 42; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3* (1912), No. 4, pp. 970, 971).—This gives the loss in weight of calves, bulls, and cows at different ages when shipped from all parts of Germany to the Berlin cattle show.

The Bordelaise breed of cattle, G. LAFFORGUE (*Vie Agr. et Rurale, 1912, No. 13, pp. 331-334, figs. 4*).—The characteristics of this French breed of cattle are illustrated and described.

The development of Bavarian cattle breeding, C. KRONACHER (*Die Entwicklung der Bayerischen Rindviehzucht. Hannover, 1911, pp. 96, fig. 56; abs. in Fühling's Landw. Ztg., 60* (1911), No. 19, p. 680).—A history of cattle breeding in Bavaria since the organization of the agricultural union a century ago.

Swiss cattle, J. DE LHARPE (*Ann. Gemblour, 22* (1912), No. 7, pp. 424-435, pls. 3).—The Swiss breeds of cattle are illustrated and described.

Sheep and wool for the farmers.—I, The cross-breeding of sheep, J. W. MATHEWS (*Dept. Agr. N. S. Wales, Farmers' Bul. 53, 1912, pp. 126, figs. 56*).—This bulletin treats of the classification of sheep breeds, principles of breeding, influence of climate upon breed, suitability of the breeds for different localities, wool production, the raising of early lambs, management of sheep, cross-bred v. Merino stock, and the standardization of the cross-breeds.

Sheep breeding in East Friesland, GROSS (*Illus. Landw. Ztg., 32* (1912), No. 49, pp. 457-459; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel.*

and Plant Diseases, 3 (1912), No. 8, p. 1817).—The characteristics of the East Friesland milk sheep are discussed, and there is a general account of the recent efforts to improve the breed.

**A comparison of sheep branding paints, C. J. OVIATT** (*Wyoming Sta. Bul.* 93, pp. 8, figs. 6).—This bulletin reports the results of tests for the purpose of ascertaining the comparative efficiency, durability, and scouring-out qualities of several commercial brands of sheep branding paints.

Paints remained a greater length of time on downs and fine wools than on coarse wool. The fineness of the wool had no effect on the scouring-out qualities of the paints. It is stated that if all wool growers would use a scourable paint the labor of clipping brands from the fleeces in the mills would be eliminated and this saving could be added to the price of wool.

"A paint made of Venetian red or lamp black as pigments mixed with linseed oil is much more durable than the prepared paints tested. The right consistency may be obtained by the addition of turpentine."

**Heredity in goats, C. J. DAVIES** (*Mendel Jour.*, 1912, No. 3, pp. 104-116, figs. 6).—Data are presented from herd books of the British Goat Society on the inheritance of horns and hair.

**Dried yeast as a food for fattening swine, W. VÖLK** (*Ztschr. Spiritusindus.*, 35 (1912), Nos. 1, pp. 1, 2; 2, pp. 14, 15; 3, pp. 25, 26; 4, p. 38; 5, pp. 48, 49; *Wechschr. Bran.*, 28 (1911), Nos. 45, pp. 537-541; 46, pp. 550-556, figs. 3; *abs. in Chem. Zentbl.*, 1912, I, No. 7, p. 515).—The average daily gain of 9 pigs for 7½ months on a ration of dried yeast, potatoes, and barley was about 0.77 kg. (1.69 lbs. per head per day at a cost of 0.545 marks (13 cts.) per day. Analyses of feeds and the slaughter weights of different organs are given.

**Swine fattening experiments with soy-bean meal, E. HASELHOFF** (*Fühling's Landw. Ztg.*, 61 (1912), No. 12, pp. 401-414).—Soy-bean meal was found to be somewhat cheaper than barley meal as a feed for swine when given with a variety of other feeds. Studies of the fat showed that soy-bean meal had no great effect on the index of refraction, saponification number, or iodine number.

**Fattening pigs, J. W. WILSON** (*South Dakota Sta. Bul.* 136, pp. 339-350, fig. 1).—To determine the comparative value of buttermilk, sweet skim milk, and sour skim milk when fed in connection with corn, experiments were conducted during the summers of 1910 and 1911. In 1910 24 pigs averaging 92 lbs. each were fed for 62 days rations consisting of about 2½ lbs. of milk for every pound of shelled corn. An equal number of pigs averaging 93 lbs. each were fed 62 days in 1911, about 3 lbs. of milk for every pound of shelled corn. Each year a lot was fed on shelled corn without milk as a check lot. All pigs had an abundance of blue grass pasture. The pigs consisted of pure bred Poland-Chinas, Duroc-Jerseys, Berkshires, and Hampshires, and grade Duroc-Jerseys. Averaging both experiments, the lot fed shelled corn made a daily gain of 1.04 lbs. each, and consumed 4.68 lbs. corn per pound of gain. Those fed shelled corn and sweet skim milk gained 1.65 lbs. each daily, requiring 3.12 lbs. of grain and 8.59 lbs. of milk per pound of gain. The lots on corn and sour skim milk gained 1.64 lbs. each daily, requiring 3.18 lbs. grain and 8.72 lbs. milk per pound of gain. The corn and buttermilk lots made a gain of 1.66 lbs. each daily, requiring 3.15 lbs. grain and 8.64 lbs. milk per pound of gain.

Another experiment was conducted to determine the practical value of the "hog motor" for fattening pigs. The hog motor is a machine with a pair of burrs so constructed that the pig is compelled to grind the grain before he receives it. In 1911 8 pigs, averaging a little over 200 lbs. each, were divided into 2 lots of 4 each and placed in yards with access to a good rape pasture. In one lot was placed the hog motor filled with shelled corn and in the other lot was placed a self-feeder filled with corn meal. The test lasted 61 days.

The hog-motor lot made an average daily gain of 1.49 lbs. each, requiring 5.63 lbs. grain per pound of gain. The self-feeder lot made an average daily gain of 1.56 lbs. each, requiring 5.72 lbs. grain per pound of gain.

**The feeding of pigs**, C. B. JONES (*Univ. Col. Wales, Agr. Dept. Bul. 1* [1912], pp. 14, 15).—In an experiment with 6 pigs which lasted about 6 weeks the 3 fed boiled potatoes gained 25 lbs. more than the 3 fed raw potatoes with otherwise similar rations. When the cost of cooking, however, was added the actual gain in money for cooked potatoes was small.

[Swine breeding], SCHIROEDER ET AL. (*Illus. Landw. Ztg., 32* (1912), No. 75, pp. 685-698, pl. 1, figs. 293).—This number is devoted especially to swine breeding, containing several articles on methods practiced by swine breeders in different parts of Germany, the cost of pork production, and related topics.

On ovariectomy in sows, with observations on the mammary glands and the internal genital organs, R. J. J. MACKENZIE and F. H. A. MARSHALL (*Jour. Agr. Sci., 4* (1912), No. 4, pp. 410-420, pls. 2).—Observations upon sows confirm the view that the ovaries are an essential factor in mammary growth, or at any rate in such mammary growth as occurs in nonpregnant animals. The mammary glands apparently undergo cyclical changes corresponding to those which take place in the internal generative organs during the estrous cycle. Changes taking place in the tissues of the mammary region in sows during heat consisted mainly of a congestion of the glands. These changes are of much importance because the part affected in the pig is of much commercial value, there being considerable loss in the quality of the bacon when animals are killed for meat during this period.

In black pigs the case was found to be complicated because of the occurrence of melanic pigment in the mammary region, but as far as the authors were able to determine this pigment is not derived from extravasated blood and has no connection with the occurrence of heat. The pigment is probably similar in kind to the melanic pigment of the hair, and the bacon manufacturer who wishes to differentiate between sows slaughtered at this period and other sows can not rely upon this pigment as a guide. Since ovulation occurs during estrum and not during proestrus it is advisable to hog the sow during the end of the period, and the practice of turning the boar loose to a considerable number of sows is deprecated.

Curing of Italian hams, J. A. SMITH ET AL. (*Daily Cons. and Trade Rpts. [U. S.], 15* (1912), No. 249, pp. 385-388).—This describes the various methods of curing hams in different parts of Italy.

Studies on horse breeding, R. MOTLOCH (*Studien über Pferdezucht. Hannover, 1911*, pp. VIII+125, figs. 13; *abs. in Zentbl. Agr. Chem., 41* (1912), No. 8, pp. 573, 574).—This discusses inheritance, inbreeding, early maturing, and related problems, based largely on experience in breeding horses in Hungary.

A brief study on the breeding of army horses in Sao Paulo, A. FOMM (*Criador Paulista, 7* (1912), No. 62, pp. 1289-1306, figs. 17).—A discussion of the type of horses needed for the Brazilian army, and methods of improvement by proper selection of breeding stock.

The Zmudian horse, I. VON MORACZEWSKI (*Mitt. Landw. Inst. Breslau, 6* (1912), No. 4, pp. 563-600, fig. 1).—A history, characteristics, and measurements are given of the native horse of Zmudz (Samogitia).

The heredity of racing stamina in the thoroughbred horse, J. B. ROBERTSON (*Mendel Jour., 1912*, No. 3, pp. 37-92).—A discussion of the physiological properties of the muscle and to what extent they are inherited. There is also a Mendelian analysis of data gathered from racing calendars and stud books in regard to types of race horses, the relative staying power of mares and horses,

the essential qualities of a "stayer," and the severity of the race-course test as a selective agent.

The author states that dark red striated muscle is correlated with a capacity for long sustained muscular effort and that an excess of a pale fiber is correlated with inability to respond to repeated stimulation. "The muscles in the heavy breeds of horse appear to be exclusively of a pale red variety. The Shire horse, even when thoroughly conditioned and fit, rapidly suffers from muscle asphyxiation if made to gallop at his top pace, poor as it is, for a short distance. . . . The physiological properties of the muscles of certain race horses are sharply defined from those of others. . . . The gametic composition of these individuals is in accordance with a Mendelian conception of alternative unit characters." "The graduated series of distances over which races are run in Great Britain and Ireland provides a test which, though perhaps not entirely free from error, is, nevertheless, a reliable standard by which an individual horse's racing stamina can be assessed."

Tables are presented to show that mares are at a disadvantage as race horses after 2 years of age.

**A note on yellow dun horses and the relation of this color to chestnut,** C. J. DAVIES (*Mendel Jour.*, 1912, No. 3, pp. 197, 198).—Some evidence is presented which throws doubt on the recessiveness of chestnut and other colors. It is also pointed out that until some distinction is made between bay and brown it will be impossible to analyze results on the inheritance of color in horses.

**The horse's foot,** E. T. ROBBINS (*Breeder's Gaz.*, 62 (1912), No. 8, pp. 305, 306, figs. 4).—A discussion of the essential points of the hoofs to be noted in buying horses, based on many years' experience of an expert buyer.

**Laying test with different breeds of poultry,** C. B. JONES (*Univ. Col. Wales, Agr. Dept. Bul. 1* [1912], pp. 17-19).—An egg-laying test is reported which lasted from December 1, 1908, to March 18, 1909. The 10 Plymouth Rock hens laid 237 eggs, the 10 Buff Orpingtons 491, and the 9 Partridge Wyandottes 508.

**Egg-laying competitions,** D. S. THOMPSON (*Dept. Agr. N. S. Wales, Farmers' Bul. 57*, 1912, pp. 14).—A summary of 10 years' work at the Hawkesbury Agricultural College and Experiment Farm, Richmond, New South Wales. The average number of eggs laid per hen was 131 in the first year's contest and 184 in the last year. There was also a noticeable improvement in the type of bird.

**Sex-limited inheritance in poultry,** C. B. DAVENPORT (*Jour. Expt. Zool.*, 13 (1912), No. 1, pp. 1-18, pls. 8, fig. 1).—A brief review of previous investigations, and a complete report of work previously noted (E. S. R., 26, p. 878) in support of the formula that sex-limited characters have their determiners in the sex chromosomes.

Reciprocal crosses were made with brown Leghorns and dark Brahmas. In the  $F_1$  crosses all males were light, but the females differed according as the brown Leghorns or the dark Brahmas were used as the father. In the  $F_2$  generation there were 2 kinds of males. The observations seem in accord with the hypothesis that the male carries 2 sex chromosomes and the female 1, and that the determiners for certain secondary sex characters are centered in the sex chromosomes, although the development of other characters seems to be especially influenced or modified by the secretions of the sex glands.

**Study in ostrich breeding,** J. L. FRATEUR (*Bul. Agr. Congo Belge*, 2 (1911), Nos. 3, pp. 371-388; 4, pp. 678-692; 3 (1912), Nos. 2, pp. 366-390; 3, pp. 719-739, figs. 57; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intl. and Plant Diseases*, 3 (1912), No. 3, pp. 747-749).—A statistical and general article on ostrich breeding in various countries. Methods of breeding and feeding are described.

## DAIRY FARMING—DAIRYING.

**Production and inspection of milk, E. V. WILCOX** (*Hawaii Sta. [Spec. Pub.], 1912, July 31, pp. XI+348*).—In this publication the author has reviewed the literature on milk and has presented detailed information under the following chapter headings: Normal milk, abnormal milk, hygiene and diseases of cows, feeding cows, buildings and premises, milking and handling milk on the farm, transportation and sale of milk, refrigeration, pasteurization and sterilization of milk, preservatives in market milk, physical and chemical examination of milk, bacteriology of milk, transmission of infectious diseases of milk, milk products in their relation to health, and history of milk inspection. A chapter by Louise Tayler-Jones is given on the dietetics of milk with reference to infant feeding.

A bibliography of milk inspection is included.

**Studies of dairy husbandry, with special reference to the capital invested, E. CAJANDER** (*Abhandl. Agr. Wiss. Gesell. Finland, 1911, No. 2, pp. 76, tables 39*).—This study is based mainly on statistics gathered by the author from 124 dairy farms in Finland. The results are presented in tabular form.

There were more cattle kept per hectare on the small farms than on the large farms. More capital was invested in buildings than in cattle, except in the group of large farms. The largest amount of capital invested per hectare was found on the large farms, but the largest amount of capital per animal was on the small farm.

**Cattle breeding in Vorarlberg, J. K. GREISENEGGER** (*Ztschr. Landw. Versuchsiv. Österr., 15 (1912), No. 8, pp. 901-1001*).—A discussion of the influence of age, weather, conformation, and other factors on milk secretion, based on the milk records and measurements of cows of the Montavon breed, which are presented in tabular form.

**The Illawarra breed of dairy cattle, F. McCAFFREY** (*Amer. Breeders Mag., 3 (1912), No. 3, pp. 164-173, figs. 5*).—This contains an account of the origin and characteristics of this type of cattle, which has become a favorite for dairying in the Illawarra district, New South Wales. It has been developed by crossing Shorthorns, Longhorns, Devons, and Ayrshires.

**Cooperative cow-testing associations in Minnesota, T. SEXAUER, C. S. CATHCART, and H. C. McMURRAY** (*Albert Lea [Minn.] State High School Ext. Bul. 1, 1912, pp. 55, figs. 12*).—This contains records of 28 herds, comprising 455 cows.

‘The best herd produced an average of 9,485 lbs. of milk and 315 lbs. of butter fat per cow, valued at \$99. The average cost of feed per cow was \$41.69, making a net profit of \$57.31 per cow. The poorest herd produced an average of 1,976 lbs. of milk and 90.7 lbs. of butter fat per cow, valued at \$27.88. The average cost of feed per cow was \$20.43, making a net profit of \$7.45. The silage-fed herds (12 herds, 216 cows) produced an average of 5,706 lbs. of milk, 220 lbs. of butter fat, and made a net profit of \$33.04 per cow. The herds that were not silage fed (16 herds, 239 cows) produced 3,850 lbs. of milk, 161 lbs. of butter fat, and a net profit of \$22.98 per cow.’

**Feeding dairy cows, C. C. HAYDEN** (*Ohio Sta. Circ. 128, pp. 183-211, fig. 1*).—This is a popular discussion of the feeding of dairy cows, in which are considered such factors as the composition of feeds, the feeds which can and should be grown on the farm, the feeds which may be purchased and their relative value, the physiological effect of the various feeds on the animal, and practical details of feeding. A table showing the amount of digestible nutrients in a large number of feeding stuffs, modified from Henry's Feeds and Feeding (*E. S. R., 24, p. 769*), is appended.

Cost of delivering a quart of milk to the consumer (*Hoard's Dairyman*, 43 (1912), No. 25, p. 859).—As estimated by a firm in Boston the cost of delivering a quart of milk to the consumer was 4.4 cts., to which must be added 0.37 ct. for shrinkage. The average price paid to the producer for 1 year was 3.9 cts. per quart, making a net cost per quart when delivered to the consumer of 8.67 cts.

The effect of sodium chlorid and cold storage upon the activities of proteolytic enzymes. W. N. BERG (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 19 (1912), Sect. VIII d, pp. 25-27*).—This is an abstract of a paper read before the International Congress of Applied Chemistry, September, 1912.

From the result of studies made with butter, buttermilk, and skim milk it is concluded that at low temperatures and in the presence of sodium chlorid the activity of a proteolytic enzyme may be inhibited if the amount of enzyme is small, whereas if the amount of enzyme is large proteolysis takes place rapidly and is apparently not interfered with by the low temperature or the chlorid. The methods used are described.

Enzym content of milk from diseased udders, H. ULMANN (*Amer. Jour. Vet. Med.*, 7 (1912), No. 8, pp. 329, 330).—Previously noted from another source (*E. S. R.*, 27, p. 287).

The chemical changes taking place in milk under pathological conditions, L. W. FETZER (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 19 (1912), Sect. VIII d, pp. 111-114*).—This is an abstract of a paper read before the International Congress of Applied Chemistry, September, 1912. The principal changes which were found to take place in the milk of cows suffering from inflammation other than tuberculosis of the mammary glands were the following:

Most milks at the beginning of the process showed a diminution of the apparent acidity. This in some instances went on until alkalinity set in and remained until the disease began to undergo resolution. The acidity then gradually rose to its normal point again.

In acute cases the total solids were high at the outset, but as the process went on there was a diminution. In some instances there was an increase in total solids-not-fat, while in others no marked change took place. Total nitrogen and protein ( $N \times 6.38$ ) increased at the outset and remained high until resolution took place. Casein diminished in some instances and remained so until the pathological condition was eliminated. Lactoglobulin (?) (serum globulin) increased until resolution set in. Albumin (?) (serum albumin) increased during the whole process, then returned to normal.

Lactose diminished gradually as the process went on, then returned back to normal. Fat and cholesterol diminished gradually until the fastigium of the process was reached, then increased again. Lecithin diminished gradually, then increased gradually as resolution was taking place.

Ash in some cases increased, but only in a few instances was a very large increase apparent. The most characteristic changes taking place in the composition of the ash were an increase in the sodium and chlorin content, a corresponding decrease in the potassium content, and in most instances a decrease in the calcium and phosphoric acid content. In all probability a determination of the chlorin content of the milk, or specifically in the ash, will furnish a clue as to whether or not the milk in question is of pathological origin.

Investigations on the presence of tubercle bacilli in milk and milk products, A. EBER (*Ztschr. Fleisch u. Milchhyg.*, 22 (1912), Nos. 8, pp. 243-249; 9, pp. 277-281; *Molk. Ztg. Berlin*, 22 (1912), Nos. 36, pp. 423, 424; 37, pp. 434-436; *Deut. Tierärztl. Wchnschr.*, 20 (1912), No. 30, pp. 457-461).—Mixed

milk and butter therefrom were found to contain tubercle bacilli, which were rarely present in unmixed milk. None of the samples of butter made on a small farm contained tubercle bacilli, whereas they were found in 15.6 per cent of the samples of creamery butter. The author advocates pasteurizing all mixed milks, because if the tubercle bacilli are present in only one lot the entire mixture is contaminated.

**A study of the bacteriological and sanitary condition of the milk supply of New York City,** M. C. SCHROEDER (*Jour. Infect. Diseases*, 11 (1912), No. 1, pp. 1-20, pls. 2, figs. 2).—Of 20,334 samples of country milk 38.14 per cent contained less than 10,000 bacteria, 32.61 per cent contained from 10,000 to 50,000, 11.81 per cent contained from 50,000 to 100,000, 13.39 per cent from 100,000 to 1,000,000, and 4.02 per cent contained over 1,000,000 bacteria per cubic centimeter.

Samples of city milk showed a higher bacterial content, not to be accounted for by the factor of time. It is suggested that it may be due in part to the use of cans and bottles which are not clean and are poorly iced in transit. Milk sold in bottles had a lower bacterial count than that sold in cans.

Some of the conclusions based on this analysis are the following: "The pasteurization of milk by the holding process, though still leaving much to be desired, reduces greatly the number of bacteria, besides destroying any pathogenic varieties. Ice is not sufficiently used to cool the milk. The average temperatures of the milk as delivered to the creameries by the dairymen, with the exception of the winter months, is still too high for milk to be shipped to New York, and has an unfavorable influence upon the milk by aiding the growth of bacteria. Greater care should be observed to obtain clean milk by sterilizing the cans and bottles. The greater part of the milk sold is from 36 to 48 hours old, but a considerable portion is from 72 to 96 hours old, and some even more than 96 hours. This is true of both raw and pasteurized milk."

**Creamery inspection,** B. H. RAWL (*N. Y. Produce Rev. and Amer. Cream.*, 34 (1912), No. 18, pp. 784, 785; *Cream. and Milk Plant Mo.*, 1 (1912), No. 1, pp. 16-19; *Cream. Jour.*, 23 (1912), No. 14, pp. 1-4).—This paper was read before the Association of National Dairy and Food Commissioners, 1912. It discusses state and federal inspection, the organization of inspection, standards for cream, and related matters.

**Butter control,** L. VUAFIART (*Ann. Falsif.*, 5 (1912), No. 46, pp. 379-384).—In determining the chemical constants of butter made under different conditions, the author found that the composition of butter made from 1 or 2 milkings, or from mixed farm milk, varied to only a slight extent. That made from morning milk contained slightly more volatile acid than that from evening milk. Keeping cream 8 days did not affect the composition of the cream, neither did bichromate of potash when used as a preservative.

**Butter making on the farm,** A. B. NYSTROM (*Washington Sta. Popular Bul.* 41, pp. 4).—Brief popular directions are given.

**The German cheese standards** (*N. Y. Produce Rev. and Amer. Cream.*, 34 (1912), No. 10, pp. 492, 493).—A translation of that portion of the report of the Unofficial Association of German Food Chemists which contains the definition of cream, half cream, and skim cheese.

**Studies on the factors concerned in the ripening of Cheddar cheese,** E. G. HASTINGS, ALICE C. EVANS, and E. B. HART (*Wisconsin Sta. Research Bul.* 25, pp. 54, figs. 6).—This bulletin presents a summary of the present knowledge of the bacteriology of Cheddar cheese and the results of a detailed study of a number of cheeses. See also a previous note (*E. S. R.*, 23, pp. 383, 679).

Tests were made to illustrate the effect of curdling on the distribution of bacteria. In all samples examined in the laboratory it was noted that a unit

volume of the whey contained less bacteria than the milk before curdling, approximately 77 per cent of the bacteria being retained in the curd. These tests were repeated under cheese-room conditions with similar results.

Whey was found to increase in acidity much more rapidly in contact with the curd than when removed as soon as the curd was cut. In one sample the whey in contact with curd was found to be 0.23 per cent more acid at the end of 10 hours than whey removed when curd was cut. With deep beakers filled with milk, the milk curdled with rennet, the curd cut and allowed to settle, and the beakers so kept as to allow no convection currents it was found that the acidity of bottom layers of whey increased much faster than that of the upper layers, the difference being in some cases 0.4 per cent.

In a cheese made from milk containing but few acid-producing bacteria the ripening was so delayed that at the end of 3 months the cheese showed spongy texture and scarcely any cheese flavor. In an experiment to show the enzymic action of lactic bacteria by the difference in rate of increase in acidity between raw and heated milk preserved with 3 per cent toluol, the daily increase in acidity of the raw milk was found to vary from 0.0012 to 0.0027 per cent and of the heated milk from 0.0005 to 0.0017 per cent. Since results of inoculation of sterile milk have shown that no growth could have taken place after addition of toluol any increase in acidity of the heated milk must have been due to the enzymes set free by the disintegrating cells that act on the milk sugar during the ripening of cheese. Some cultures of *B. lactis acidi* produced inactive acid, some dextro-acid, and some mixtures of the two. One culture from another source produced pure levo-acid.

In studying the percentage of acidity produced by lactic bacilli in milk to which peptone had been added, it was shown that the cessation of their growth in milk when a certain percentage of acidity is reached is not brought about by the antiseptic action of the acid, but by a lack of suitable nitrogenous food.

The development of *B. lactis acidi* was followed by the growth of the *B. bulgaricus* group. They reach numbers comparable with those of the first group, reaching their maximum numbers within the first month of the ripening. Since they developed after the fermentation of the sugar, they must have some other source of carbon and of energy than milk sugar. Coccus, chromogenic, and liquefying types were found and other tests were made which confirmed the work of previous investigators.

A new use for whey (*Molk. Ztg. Berlin, 22 (1912), No. 35, pp. 409, 410*).—A note concerning a new beverage that can be made from whey, and which is called whey lemonade. The method of making is not described.

Tätté, the original preserved curd of the North, and other fermented milks; their significance for the nutrition of man, O. J. OLSEN-SOPP (*Centbl. Bakt. [etc.], 2. Abt., 33 (1912), No. 1-6, pp. 1-54, pl. 1; abs. in Internat. Inst. Agr. [Roum], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 6, pp. 1433-1435*).—Tätté is prepared from milk while still warm from the cow, by adding some of the old curd which has been dried on straw or linen cloths. The organisms present depend somewhat on the age of the preparation, but *Streptobacillus tätté*, *Lactobacillus tätté*, and *Saccharomyces tätté* were always found, and quite frequently species of *Monilia*, *Torula*, and *Lactococcus*. *Oidium lactis* was common when the preparation was of poor quality.

"Cellar milk" is another form of fermented milk made in Sweden and Norway, and used by the inhabitants of the valleys when the cattle are kept in the mountains during the summer. It is prepared from fresh milk by adding water, boiling, and placing it in the cellar in large wooden vessels previously scalded with a juniper decoction and then rubbed with tätté. The vessels are covered with muslin and the milk after the first week is well mixed every

day. It has the characters of good sour milk and does not grow moldy or putrefy throughout the summer.

**Officials, organizations, and educational institutions connected with the dairy interests, 1912** (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 204*, pp. 26).—This is a revision of Circular 162, previously noted (*E. S. R.*, 23, p. 676).

## VETERINARY MEDICINE.

**Handbook of veterinary surgery and obstetrics**, edited by J. BAYER and E. FRÖHNER (*Handbuch der Tierärztlichen Chirurgie und Geburtshilfe. Vienna and Leipzig, vols. 1, 1910, 4. ed., pp. XVI+745, figs. 562; 2, 1911, 4. ed., pp. XVI+340; 3, 1908, pt. 2, pp. VIII+442, figs. 78; 3, 1911, pt. 3, pp. VIII+298, pls. 5, figs. 77; 4, 1908, pt. 1, 2. ed., pp. XI+646, figs. 152; 4, 1908, pt. 2, pp. X+680, pls. 6, figs. 270; 5, 1906, 2. ed., pp. XIII+536, pls. 17, figs. 279; 6, 1908, 2. ed., pp. XV+572, pls. 8, figs. 95; 7, 1910, pt. 1, 3. ed., pp. XV+420, figs. 90*).—This work by various authors treats of the subject as follows: Volume 1, operative technique, by J. Bayer; volume 2, general surgery, by E. Fröhner; volume 3, parts 2 and 3, the head, neck, chest, and abdomen, by E. Hess et al.; volume 4, part 1, the extremities, by several authors and part 2, hoof diseases of the horse, by R. Eberlein; volume 5, diseases of the eye, by J. Bayer; volume 6, skin diseases, by H. Schindelka; and volume 7, bovine obstetrics, by M. G. de Bruin.

**The diagnosis of pregnancy in animals by the optical and dialysis methods**, E. ABDERHALDEN and A. WEIL (*Berlin. Tierärztl. Wehnschr.*, 28 (1912), No. 36, pp. 665-667).—This is a continuation of the studies noted (*E. S. R.*, 27, p. 577). The investigation, which was made with 12 cows, gave positive results in 10 cases. The dialysis method is easier to conduct, but the nature of the cleavage process can not be determined. The method of conducting the tests is given in detail.

**The colloids in biology and medicine**, H. BECHHOLD (*Die Kolloide in Biologie und Medizin. Dresden, 1912, pp. XII+444, pls. 2, figs. 52*).—The purpose of this book is to point out the colloid phenomena which occur in biology and medicine. It includes an introduction to the methods of colloid investigation, and a discussion of the biocolloids (carbohydrates, lipoids, proteins, foods and condiments, enzymes, and immunity reactions), the organism as a colloidal system (metabolism, the cell, blood, respiration, resorption and secretions, secretions and excretions, etc.), toxicology and pharmacology, and microscopical technique. A bibliography is appended.

**The passage of drugs into the sweat**, H. TACHAU (*Arch. Expt. Path. u. Pharmakol.*, 66 (1911), No. 5-6, pp. 334-346; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 592, II, pp. 184, 185).—Iodin, bromin, boric acid, phenol, salicylic acid, salol, antipyrin, and methylene blue were found to be excreted in the sweat but the amount was small, as they pass into the milk and other secretions. The amount may be sufficient, however, to cause skin eruptions in certain cases.

**The chemical examination of death camas**, F. W. HEYL ET AL. (*Wyoming Sta. Bul. 94*, pp. 3-31, figs. 3).—The work here reported relates to *Zygadenus intermedius*, also known as poison camas, lobelia, squirrel food, wild onion, poison sego, poison sego-lily, mystery grass, etc. The alkaloid found in this plant is most abundant in the flowers, which contain approximately 1.25 per cent. The bulb and the leaves and tops contain approximately 0.6 per cent, and the roots but half that amount. Guinea pigs, dogs, and frogs were used in determining the physiological effect of the alkaloid and the antidotes.

The experiments led to the following conclusion: "The alkaloidal preparation from *Z. intermedius* slows the heart rate by acting apparently on the cardio-inhibitory center. It slows respiration by an effect involving the respiratory center. It causes vaso-dilation. In quantities approaching the fatal dose it hastens the heart rate and produces both irregularity of the heart beat and convulsive respiration. The fatal dose given intravenously to dogs stops the heart before respiration ceases. The fatal dose for guinea pigs is between 4.6 and 5.1 mg. per 100 gm. of animal. It has a very powerful action, whether injected or fed, both as a purgative and an emetic."

In order to ascertain the pharmacological properties of the resin present a series of experiments was conducted, the results of which demonstrated it to be physiologically inert.

**The effect of Tilletia in the food of domestic animals, G. PUSCH** (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 11 (1912), No. 1, pp. 1-14).—The investigations here reported have led the author to conclude that domestic animals may consume large quantities of wheat smut spores for a long period without ill effect; and that gestating ruminants and swine may consume large amounts of smutty wheat without aborting.

**A mycotic enzootic caused by blighted barley, C. DARMAGNAC** (*Abs. in Vet. Jour.*, 68 (1912), No. 445, pp. 434, 435).—A brief report of forage poisoning in 21 horses caused by feeding on barley injured by smut (*Ustilago carbo*).

**Destruction of bacteria by leucocytes, S. SUZUKI** (*Arch. Hyg.*, 75 (1912), No. 4-5, pp. 224-234).—A systematic quantitative study of cytolytic activity of leucocytes toward various micro-organisms was made. It was noted that with the fairly sensitive micro-organisms, leucocytes in doses of 0.025 gm. are strongly bactericidal. In the case of the less sensitive micro-organisms, e. g., typhoid, cholera, and fowl cholera, the cytolytic activity ceases with the minimum doses, and even with quantities of 0.5 gm. this activity is very weak, and amounts of from 0.1 to 0.15 are necessary. Leucocytes in 0.025 gm. doses were more effective against the hog erysipelas bacterium than larger doses.

**The development of a leucocytozoon of guinea pigs, E. H. ROSS** (*Ann. Trop. Med. and Par.*, 6 (1912), No. 1, pp. 69-76, pl. 1).—"Kurloff's bodies are parasites, lymphocytozoa inhabiting only the mononuclear cells of the guinea pig's blood. These lymphocytozoa have an intracorpuseular stage, and ultimately give rise to free-swimming, spirochete-like bodies, which may be gametes. The development of the spirochete-like body is demonstrated. The name *Lymphocytozoon cobaya* is suggested for this parasite."

**The new mycoses, DE BEURMANN and GOUGEROT** (*Les Nouvelles Mycoses. Paris, 1912, pp. 165, figs. 16*).—This work deals with the exascoses (ex-blastomycoses), oidiomycoses, sporotrichoses, botrytimycosis, oösporoses, and hemisporosis.

**Immunity facts and the outlook, H. MUCH** (*Würzb. Abhandl. Gesam. Geb. Prakt. Med.*, 9 (1909), No. 6-7, pp. 117-184).—This is a comprehensive digest of the facts relating to immunity. It deals particularly with the present knowledge of the subject as applied to both human and veterinary medicine.

**In regard to opsonins, A. FRENZEL** (*Ueber Opsonine. Inaug. Diss., Univ. Leipsic, 1911, pp. 87*).—The Wright method for determining the opsonic index was found to be satisfactory and the percentage of errors was never greater than 10 per cent. The opsonic index of normal individuals, man and animals, was found to vary between 0.9 and 1.1. The indexes of infected individuals, which included tubercular humans and bovines, and humans with staphylococcal infections, were found to be in from 40 to 50 per cent of the cases within the normal figure, while all the rest had subnormal or hypernormal indexes. The behavior of blood sera of sound horses and other domesticated animals

toward *Streptococcus equi* was found to be the same as with the tubercle bacillus and the staphylococcus (between 0.9 and 1.1).

In the work it was also shown that very large doses of the staphylococcus vaccine (and likewise opsonogen) are harmless to the animal organism (guinea pigs, rabbits, and dogs). The local treatment which was instituted by Wright and Strubell against staphylomycoses without determining the opsonic index was very satisfactory.

**Contribution to our knowledge of antiaggressin sera.** F. NEUFELD and KANDIRA (*Arb. K. Gsndhtsamtl.*, 40 (1912), No. 1, pp. 1-23).—After reviewing the aggressin theory and pointing out some of its unexplained features, the authors sought to determine whether a hitherto unrecognized antibody plays a rôle in the activity of anthrax and erysipelas immune sera. For the tests, which were made *in viro* and *in vitro*, a highly immune erysipelas serum and *Bacillus crysipelatis* were employed.

The results showed that a specific bacteriotropic action was present in most of the cases, and this, according to the authors, explains the reason for the protective and curative properties of the serum. While phagocytosis is present in normal animals the phagocytic manifestations were found to occur somewhat sooner in pathologic animals. The reason for believing that an antiaggressin immunity exists is therefore remote.

**The sero-diagnosis of echinococcus disease.** W. PFEILER (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 11 (1912), Nos. 1, pp. 70-96; 2, pp. 153-169, 3-4, pp. 255-304).—This is a monographic study of the value of the various biological reactions for diagnosing hydatid disease. A bibliography of 152 titles is appended.

**Ascoli's reaction (thermoprecipitin) for diagnosing erysipelas.** P. SILVA (*Clin. Vet. [Milan]. Rass. Pol. Sanit. e Ig.*, 35 (1912), No. 4, pp. 145-149).—A specific antigen can be prepared from fresh or putrefied organs from animals affected with erysipelas. This antigen when tested with a specific serum will give a characteristic Ascoli reaction. In these tests no reaction was obtained with the serum from healthy hogs or hogs affected with infectious pneumonia.

**A case of swine erysipelas in man.** LINSER (*Dermatol. Ztschr.*, 18 (1911), No. 4, pp. 352-354, fig. 1).—The author reports a case of this disease in a butcher who injured his left hand while slaughtering a diseased hog. The injection of 25 cc. of swine erysipelas serum (Susserin) resulted in a cure in 3 days.

**Enteritis, associated with infection of the intestinal wall by cyst-forming protozoa (neosporidia), occurring in certain native animals (wallaby, kangaroo, and wombat).** J. A. GILRUTH and L. B. BULL (*Proc. Roy. Soc Victoria*, n. ser., 24 (1912), No. 2, pp. 432-450, pls. 10).—In this paper what appear to be 4 varieties of pathogenic neosporidia are described as seen in intestinal affections of 3 different genera of native animals, namely, *Sarcocystis macropodis* in the wallaby; *Ileocystis macropodis* and *Lymphocystis macropodis* in the kangaroo; and *Ileocystis wombati* in the wombat.

**Theory and technique of the Wassermann reaction for detecting glanders.** W. W. FEDDERS (*Viestnik Obshch. Vet.*, 1901, Nos. 8, 9, 10, 11; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 49 (1911), No. 6, pp. 175, 176).—This is a theoretical discussion in regard to the mechanism of the complement fixation reaction (E. S. R., 25, p. 181), and gives practical directions for conducting it. The specificity of the reaction is disturbed if the animal has been previously injected with mallein.

**Increased toleration to mallein.** K. DROGASHEVSKÏĀ (*Arch. Vet. Nauk. [St. Petersburg.]*, 41 (1912), No. 2, pp. 181-187; *abs. in Berlin. Tierärztl. Wchnschr.*, 28 (1912), No. 30, p. 549).—As a result of treating 200 horses with mallein the

conclusions reached are as follows: (1) Repeated injections of mallein accustom the horses to mallein. A weak reaction or none is obtained when the test is repeated. (2) The results obtained with repeated injections can not serve as a diagnostic aid unless a sufficient length of time elapses between each injection. (3) Malleinization, with the doses usually employed and in periods of 1 month apart, will not show any curative properties for glanders.

**Malta fever in Arizona, with a preliminary report of cases, C. E. YOUNT and R. N. LOONEY** (*South. Cal. Practitioner*, 27 (1912), No. 6, pp. 257-261).—The authors report 5 cases of Malta fever in man, thus indicating the occurrence of this disease among goats in Arizona.

**Spontaneous nephritis in wild rats, W. OPHÜLS and G. W. MCCOY** (*Jour. Med. Research*, 26 (1912), No. 2, pp. 249-255, pl. 1).—"Wild rats very frequently (at least in 2 per cent of all cases examined) suffer from a peculiar type of chronic nephritis, one of the characteristic features of which is a very marked tendency to epithelial proliferation and to cyst formation. A condition very similar in all respects to this spontaneous disease may be produced experimentally in white rats by subcutaneous injection of uranium nitrate."

**Rabies and its control in New York State, J. G. WILLS** (*N. Y. Dept. Agr. Bul.* 29, 1911, pp. 307-330).—A general account.

**On sporotrichosis, L. DE BEURMANN, TRANS. BY R. W. MACKENNA** (*Brit. Med. Jour.*, 1912, No. 2693, pp. 289-296).—A general discussion of this disease, the existence and importance of which have been demonstrated.

**A contribution to the study of canine piroplasmosis, N. N. NAVROTSKY and P. V. BÉRENSKY** (*Arch. Sci. Biol. [St. Petersburg]*, 17 (1912), No. 1, pp. 31-60, figs. 6; *abs. in Amer. Vet. Rec.*, 41 (1912), No. 6, pp. 639-642).—This paper takes up the clinical appearance of the disease, the condition of the blood and of the urine, the anatomo-pathologic lesions, and the virus.

**Trypanosomes obtained by feeding wild *Glossina morsitans* on monkeys in the Luangwa Valley, northern Rhodesia, A. KINGHORN and W. YORKE** (*Ann. Trop. Med. and Par.*, 6 (1912), No. 3, pp. 317-324, fig. 1).—The trypanosomes *Trypanosoma rhodesiense*, *T. pecorum*, *T. ignotum*, and probably also *T. vivax* and *T. nannum*, are transmitted in nature by *G. morsitans* in the Luangwa Valley.

**[The occurrence of dourine ("Mofo") in Ceará, Brazil], M. SABOIA** (*Sobre a Trypanosomiase dos Équidos, Conhecida no Ceará pelo Nome de "Mofo." Rio Janeiro*, 1912, pp. 64, pls. 8).—The author has succeeded in isolating a trypanosome from sick horses which is apparently *Trypanosoma equiperdum*, the causative agent of dourine. The disease, known in Brazil as "Mofo," has existed as an epizootic for several years in certain districts of that country; the syndrome resembles dourine in every particular.

**A note on the morphology of a strain of *Trypanosoma equiperdum*, W. YORKE and B. BLACKLOCK** (*Brit. Med. Jour.*, 1912, No. 2696, p. 473, figs. 14).—This note relates to stumpy forms of this parasite which have the macronucleus displaced toward the posterior end.

**Note on surra, E. W. OLIVER** (*Dept. Land Records and Agr. United Prov. Agra and Oudh, Agr. Scr.*, 1912, Bul. 27, pp. 4, pl. 1).—A brief general account with directions for prevention and treatment.

**Relation between human and bovine tubercle bacilli, G. S. WOODHEAD** (*Lancet [London]*, 1912, I, No. 22, pp. 1451-1457; *abs. in Jour. Amer. Med. Assoc.*, 59 (1912), No. 1, p. 70).—Bovine tubercle bacilli are not considered a negligible quantity as far as tuberculosis in man is concerned. Surgical and abdominal tuberculosis in man will, according to the author's belief, be found to have a direct relation to bovine tuberculosis.

**The relative importance of the bovine and human types of tubercle bacilli in the different forms of tuberculosis.** W. H. PARK and C. KRUMWIEDE (*Jour. Med. Research*, 27 (1912), No. 1, pp. 109-114).—This is a final summary of the cases investigated by these authors (E. S. R., 22, p. 390), and which shows that on the whole bovine infections cause somewhat less than 10 per cent of the total deaths in young children.

**Passage tests with human tuberculous material according to Eber's method.** F. NEUFELD, H. DOLD, and E. A. LINDEMANN (*Centbl. Bakt. [etc.], 1. Abt., Orig.*, 65 (1912), No. 6-7, pp. 467-481).—As a result of several passage experiments the conclusion is reached that human tubercle bacilli can not be converted into the bovine type by Eber's method (E. S. R., 26, p. 680).

**The use of the Millon reagent for the examination of tuberculous excretions.** B. NICOLA (*Riv. Ig. e Sanit. Pub.*, 22 (1911), No. 10, pp. 296-304; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 5 (1912), No. 11, p. 115; *Chem. Abs.*, 6 (1912), No. 18, p. 2672).—It is concluded that Millon's reagent will give useful results for the examination of tuberculous pus, but can not be used for differentiating tuberculous from nontuberculous pus. It is not serviceable for the first stages of the disease.

**Complement-fixing antibodies and tuberculosis.** B. MÖLLERS (*Centbl. Bakt. [etc.], 1. Abt., Ref.*, 54 (1912), Beiheft, pp. 202-212).—The injection of tuberculin in large doses or of killed tubercle bacilli causes the formation of complement-fixing antibodies. The greatest amount of antibodies are produced with the dead bacilli when injected intravenously. The results obtained by the complement-fixing method can not at the present time be entirely relied upon for prognostic or diagnostic purposes.

**A phosphatid as an activator for tuberculin.** H. J. BING and V. ELLERMANN (*K. Danske Vidensk. Selsk. Forhandl.*, 1912, No. 2, pp. 153-167; *Biochem. Ztschr.*, 42 (1912), No. 4, pp. 289-301; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1912), No. 1, p. 399).—A diamino phosphatid albin, was prepared from egg yolks and has the property of stimulating the cutaneous reaction obtained with tuberculin. None of the other lipoids (lecithin, cephalin, cholesterol, oleic acid, sodium oleate, etc.) has the same properties. The activation of tuberculin is possibly of significance as to the action of tuberculin upon the tubercular organism.

**Tuberculosis.** M. A. MÉTIN (*Rev. Vét. [Toulouse]*, 37 (1912), No. 10, pp. 615-623).—This is a discussion of the budget granted in France for combating tuberculosis in 1913, together with indemnities for condemned animals suffering from tuberculosis, glanders, and pneumonia. Mention is made of the decrease of contagious diseases and of the methods prescribed for combating them.

**About a case of tuberculosis in a horse.** W. GREYER (*Deut. Tierärztl. Wehnschr.*, 20 (1912), No. 43, pp. 657-659, fig. 1).—A description of the autopsical findings with a horse affected with generalized tuberculosis.

**Tuberculosis in dairy cattle.** E. M. RANCK (*Mississippi Sta. Circ.*, 1912, Aug., pp. 35, figs. 13).—This is a reprint of a report previously noted (E. S. R., 26, p. 378), with brief suggestions as to the inspection of dairies.

**Notes on infectious abortion in cattle.** F. M. SURFACE (*Science*, n. ser., 36 (1912), No. 926, pp. 409-412).—This is a brief résumé of investigations conducted in the United States and Europe in regard to infectious abortion in cattle. The biological reactions for detecting the disease and the factors which are instrumental in disseminating it are discussed.

**Investigation in regard to the biology of the Bacillus abortus and infectious abortion in bovines.** H. HOLTH (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 10 (1911), No. 4, pp. 207-273, fig. 4; *abs. in Hyg. Rundschau*, 22

(1912), No. 11, p. 717).—This is a critical study of the morphology and biology of *Bacillus abortus*, the patho-anatomical changes which are present in aborting bovines, the avenues of infection, and the occurrence of anti-substances in the blood of spontaneously and artificially infected animals, with particular reference to active and passive immunity.

It is shown that the production of agglutinins and amboceptors in artificially infected animals is variable, and that much depends upon the method of introducing the vaccine and whether dead or living organisms are employed. Experimental data are also presented in regard to the behavior of chemical and thermal agencies against the immunizing and anti-substances. In addition some immunizing and protective tests with rats and mice are reported, which show that spotted rats acquire a decided immunity against this organism when treated with killed cultures or culture filtrates of *Bacillus abortus*.

Therapeutic tests with curative lymph (Gans) and colpitol (Gans) for contagious vaginal catarrh in bovines, A. GÖHLER (*Centbl. Bakt. [etc.]*, 1. *Abt., Orig.*, 65 (1912), No. 6-7, pp. 515-538).—Gans' curative lymph was found to have only a slight curative power for this disease. Colpitol, on the other hand, affected cures in 30 per cent of the cases, and in all instances where employed improvement was noted in from 16 to 18 days.

Check list of helminths parasitic in cattle, R. T. LEIPER (*Jour. London School Trop. Med.*, 1 (1912), No. 2, pp. 115-123).—A systematic list of the helminth parasites of *Bos taurus*, *Buffelus indicus*, and *Bibos indicus* is followed by an alphabetical list of helminths in cattle and a second list of new genera and species of helminths recorded in 1911.

The introduction of air into the jugular vein, F. CHAMBERS (*Vet. Jour.*, 68 (1912), No. 445, pp. 445, 446).—The author reports experiments made to determine the minimum quantity of air which will kill a bovine when injected into the jugular vein. In the first case, a heifer 3 years old, it took 2,346 cc. of air administered in 12 minutes to cause death; in the second case, that of a 2-year old ox, it took 2,500 cc. of air injected in a period of 4½ minutes to cause death; in the third case, that of 5-year-old cow, 3,000 cc. of air administered quickly caused the death of the animal in 1 minute.

Successful vaccination against pluriform septicemia in sheep, ANDERS (*Berlin. Tierärztl. Wehnschr.*, 28 (1912), No. 38, pp. 701, 702).—In certain districts in Germany quite a number of deaths in lambs occurred as a result of pluriform septicemia. Vaccinations were made with Miessner and Schern's serum in 1908, 1911, and 1912, and these reduced the mortality considerably. Out of 700 4-week-old sheep, which were vaccinated intravenously in 1912, only 10 died.

Antisheep pox vaccination with heated virus, E. DUCLOUX (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 16, pp. 709, 710; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, *Ref.*, 6 (1912), No. 1, pp. 380, 381).—Continuing the work previously noted (*E. S. R.*, 27, p. 583) results are now reported which were obtained with 650 sheep. Of these animals 590 were treated with 0.5 cc. of heated virus, followed 7 days later by an injection of virulent virus, and the remaining 60 animals kept as controls.

Of the treated animals 582 showed no reaction toward the injection, 7 showed a slight growth at the site of injection, and 1 had a slight edema. Of the control animals 56 were markedly affected with the pox.

The method of preparing the vaccine has been slightly modified.

Congenital bronchial strongylosis in sheep, NEVEU-LEMAIRE (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 20, pp. 1311, 1312).—The author records observations of the occurrence of adults of *Dictyocaulus filaria* in 2 young lambs in which the infestation must have taken place prior to birth.

"Mal de Lure:" A pyemia secondary to contagious agalactia of the sheep and goat, H. CARRÉ (*Ann. Inst. Pasteur*, 26 (1912), No. 4, pp. 281-299, pl. 1, figs. 2).—The author has found "mal de Lure," which develops secondary to contagious agalactia in sheep and goats, to be due to a new pyogenic bacillus, to which he has given the name "pyobacillus of the sheep and goat." This affection was prevalent during 1911 in the Lure mountain district of southeastern France. The disease is manifested by a purulent sloughing condition of the eyes and udder, suppurative arthritis of the knees, stifles, and hips, and a progressive muscular wasting.

Hog cholera, E. L. MOORE and T. B. KELLY (*South Dakota Sta. Bul.* 138, pp. 370-391, figs. 5).—This bulletin consists largely of a general account of hog cholera, including post-mortem appearances, prevention by artificial immunity, the method of producing and testing potent serum, method of vaccination, sanitary measures, etc.

The results of investigations indicate that there is no constant relation between the agglutination reaction of immunizing serum for *Bacillus cholerae suis* and its potency as shown by actual field trials. Thus it can not be used as a method of standardizing serums for commercial purposes.

Investigations made to determine the value of the salt solution recovered from the intraperitoneal cavity of hogs killed with acute cholera for hyperimmunization purposes are briefly reported and considered very satisfactory, the virulence of the recovered salt solution having met the standard requirements. The authors state they can see no reason why it can not be used successfully in hyperimmunization work.

New sero-therapeutic tests for hog cholera, P. STAZZI (*Berlin. Tierärztl. Wchnschr.*, 28 (1912), No. 38, pp. 697-701).—After giving the geographical distribution of the disease in the districts around Pavia and Milan, Italy, and the preparation of hog-cholera serums, the results of a comparative investigation of the protective value of Hutyra's and L. W. Gans' serums, and the serums prepared at the experiment station for infectious diseases of domesticated animals of the Agricultural Association of Milan, are reported.

In the first series of tests 38 shotels, 3 months old, weighing from 20 to 22 kg., were treated as follows: Ten received the Milan serum, 20 Gans' serum, and 8 animals were injected with Hutyra's serum. All of the animals mentioned above and 6 control animals received injections after the second day of 2 cc. of blood obtained from strongly infected animals. Four of the 6 control animals died within 15 to 20 days, and the other 2 went through the course of a light form of the disease. Of the animals treated with the Milan serum and the Gans serum 1 succumbed in each case, while with Hutyra's serum none of the animals became sick. A second set of experiments conducted under the same conditions gave less favorable results.

In a second series of tests in which an attempt was made to simulate practical conditions animals having natural hog cholera, and others artificially infected, were used. These animals with some controls were housed in the station barns. Far better results were obtained from these tests than from the first series. All of the control animals died of an acute hog cholera, while out of 21 treated animals only 1 died.

It is pointed out that the serum confers marked immunity, which, however, may not be absolute. The curative action of Gans' new serum was found to be very slight or nil.

Immunizing against swine plague, ROELCKE (*Arch. Wiss. u. Prakt. Tierheilk.*, 37 (1911), No. 4, pp. 367-381; *abs. in Berlin. Tierärztl. Wchnschr.*, 28 (1912), No. 6, p. 105).—By treating experimental animals with carbolized cultures of the swine-plague bacillus an increased resistance toward experimental

infection can be obtained, but not an absolute protection since carbolic acid itself has some effect upon the antigen.

The possibility of utilizing glycerol cultures as a vaccine against swine plague was proved. Precaution, however, must be taken that the glycerol and culture are present in the ratio of 1:1. An excess of glycerol must be avoided.

Investigations in regard to the agglutination of paratyphoid and pestifer strains, TEODORASCU (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 14 (1912), No. 6, pp. 639-646; abs. in *Centbl. Bakl.* [etc.], I. Abt., Ref., 54 (1912), Beiheft, pp. 83, 84).—A number of strains of the organisms belonging to the paratyphoid group were isolated from man and pig, and compared as regards their agglutinating properties with paratyphoid, suipestifer, Voldagsen, and Glässer serums. The results agree well with those obtained previously by Haendel and Gildemeister (*E. S. R.*, 26, p. 785).

The effect of wheat eating by horses, W. T. KENDALL (*Aust. Farm and Home*, 21 (1912), No. 8, pp. 376, 378).—The author, having conducted a series of feeding experiments on horses, here gives a brief account of the symptoms, causes of death, and treatment.

A contribution to the study of infectious epididymo-vaginalitis of the horse, C. MEDYNSKI (*Bul. Soc. Cent. Méd. Vét.*, 89 (1912), No. 4, pp. 99-106).—The author reports clinical and laboratory studies made of this disease, first recognized and studied in Havre by Vallée, Lesueur, and Lavergne in 1905<sup>a</sup> and by Guido Finzi in 1910 (*E. S. R.*, 24, p. 485). He finds that the serum from sick or convalescing animals agglutinates Vallée's bacillus in a dilution of 1:200 whereas at the onset of the disease agglutination took place only at a dilution of 1:10. The injection of diseased animals daily for a period of 5 days with 100 cc. of serum obtained from a convalescing animal resulted in rapid improvement.

Certain concretions in a cyst of the mammary gland in a horse, A. SCHEUNERT and W. GRIMMER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 76 (1912), No. 4, pp. 322-329; abs. in *Jour. Chem. Soc.* [London], 102 (1912), No. 592, II, p. 186).—The concretions examined gave the following percentages: Water 69.0, protein 4.5, fat 13.7, cholesterol 10.0, lecithin 0.7, and ash 1.7. The fat somewhat resembled colostrum fat, being intermediate between milk fat and the body fat of the horse. Casein was absent.

Check list of helminths parasitic in equines, R. T. LEIPER (*Jour. London School Trop. Med.*, 1 (1912), No. 1, pp. 22-26).—Systematic and alphabetical lists are given. See also a previous note (*E. S. R.*, 27, p. 583).

Report of the bacteriological institute of the agricultural chamber of Rheinisch Prussia (*Jahresber. Landw. Kammer Rheinprov.*, 1911, pp. 70-76).—This is a report in regard to the activities of this institution for the year 1911. It deals with the results of combating tuberculosis in animals; tests in regard to combating various infectious diseases, such as vaginal catarrh; determination of the cause of death in animals; and destruction of mice, rats, etc., with mouse typhoid cultures.

## RURAL ENGINEERING.

Cooperation in water power and irrigation, J. H. LEWIS (*Pacific Builder and Engin.*, 14 (1912), No. 12, pp. 246-248).—This is a paper presented before the Development League Conference, at Lakeview, Oreg., in August, 1912, dealing with the exercise of state credit in developing arid lands and water powers.

It is claimed that most of the large commercial enterprises undertaken by

<sup>a</sup> *Bul. Soc. Cent. Méd. Vét.*, 82 (1905), No. 14, pp. 333, 334.

private capital and nearly all the state projects under the Carey Act have failed because of the lack of adequate engineering and complete financial plans, and because of inexperience on the part of the State and interested parties in obtaining good work. It is suggested that since the future prosperity of the State depends in a large measure upon the construction of the large irrigation works, the State should cooperate with the United States Reclamation Service and authorize a bond issue for the construction of irrigation and power projects—the money when invested to be made a lien upon the land irrigated and works constructed to insure its return in from 20 to 40 years with interest, thereby securing development without increasing taxation.

It is concluded that by this method much water power can be developed auxiliary to construction, thus reducing the burden on the irrigator, and that by cooperating with the United States Reclamation Service the state funds can be invested without running the risk of failure because of an inexperienced state department.

**Triennial irrigation revenue report of Sind for the triennium ending 1910-11** (*Tricn. Irrig. Rev. Rpt. Sind, 1908-9—1910-11, pp. V+84+2+2, pls. 7*).—This is the fourth triennial revenue report on irrigation works in Sind, containing statistical information, statements showing the working details and results attained on each project in 4 successive triennial periods, and brief general remarks.

[Modern irrigation methods] (*Nat. Land and Irrig. Jour., 6 (1912), No. 1, pp. 14-16, figs. 4*).—This article deals with past and present irrigation methods, presenting as conclusions that earth ditches are wasteful, costly, and shiftless; that wooden flumes are expensive, temporary, and wasteful; that concrete flumes are perishable, obstructive, and wasteful; and that a concrete pipe underground is a perfect water distributor, cheap in installation, durable, cheap in maintenance, standing very high internal pressures when reinforced, and if skillfully made with suitable materials considerable pressure without reinforcement.

**Application of hydro-electric energy to irrigation pumping in southern Idaho, E. A. WILCOX** (*Elect. World, 60 (1912), No. 14, pp. 705-710, figs. 13*).—This is a description of various installations with data on water requirements and considerations governing rates for service.

It has been found much cheaper and better to water a large tract of land with one large pumping plant than with a number of smaller ones, since the machinery efficiency is greater, the seepage and evaporation losses are reduced, and the cost of installation is lowered. The older data on water requirements called for a depth of 4 ft. or more annually, but recent tests show that a fraction of this is sufficient for most crops and soils. The demand for water runs over 6 months, from April to September inclusive; more than half of the total requirements falling in June and July and the load factor for the 6 months' season being about 0.5.

The energy required for pumping is directly proportional to the lift and to the quantity of water lifted. The cost of energy is based on the consumer's highest half hour peak as shown by a recording meter, the price being commonly \$20 per horsepower for the 6 months' season. The generating equipment is used in winter for supplying heat for homes, offices, stores, etc., the heating load being taken on at a flat rate varying with the size and character of the installation.

**Experiments of 1908-1910 on lining of water courses to reduce absorption losses, F. W. SCHÖNEMANN** (*Punjab Irrig. Branch Papers, 1912, No. 11-c, pp. 70, pls. 11*).—A large amount of absorption and evaporation data showing the efficiencies of different linings is presented.

Costs of mortar lining on irrigation canals. H. D. NEWELL (*Engin. News*, 68 (1912), No. 15, pp. 651-653, fig. 1).—This article gives cost data on the lining of irrigation canals in the Umatilla project of the United States Reclamation Service, including engineering, equipment, materials, and labor.

Canal M, 12,409 ft. long having a bottom width of 4 ft., depth 4 ft., and side slopes  $1\frac{1}{4}:1$ , was lined with 1:4 cement mortar  $1\frac{1}{2}$  in. thick, with a top curb 4 in. wide and 3 in. thick, at a total cost of \$13,969.91 or 55 $\frac{1}{2}$  cts per square yard. Canals L, T, and A, with side slopes of  $1\frac{1}{4}:1$  and varying from a bottom width of 4 ft. and depth of  $3\frac{1}{2}$  ft. to a bottom width of 1 ft. and depth of  $1\frac{1}{2}$  ft. were lined where lining was most needed with 1:4 cement mortar,  $1\frac{1}{2}$  in. thick, at respective costs of \$1,635.62 or 48.9 cts. per square yard, \$4,633.70 or 62 $\frac{1}{2}$  cts. per square yard, and \$2,026.76 or 64.2 cts. per square yard. A series of gagings indicates that the lining placed has practically eliminated seepage losses.

Reclaiming Minnesota swamp lands, G. A. RALPH (*Farm Implements*, 26 (1912), No. 8, pp. 36, 40).—A summary of 6 years' drainage work in Minnesota, showing the reclamation of 6,250,000 acres of swamp land at a total cost of \$10,008,608 and an estimated benefit of \$18,778,915.

Filling a swamp with a pump, C. H. CLARK (*Amer. Cult.*, 74 (1912), No. 37, p. 2, figs. 4).—A new method of swamp land reclamation, in which a dike was constructed inclosing the flat swampy end of a lake and electrically driven centrifugal pumps were used to pump out the surplus water and to wash the soil from the surrounding hills for filling in the swamp, is described.

The char-pit method of destroying stumps, H. W. SPARKS (*Washington Sta. Popular Bul.* 40, pp. 8, figs. 5).—A summary of data previously noted (*E. S. R.*, 26, p. 787).

New state road law in Arizona (*Good Roads, n. scr.*, 4 (1912), No. 14, pp. 144-146).—A new set of road laws regulating road administration, financing, construction, and maintenance in Arizona.

Benefits of improved roads (*U. S. Dept. Agr., Farmers' Bul.* 505, pp. 20, figs. 8).—This publication deals with the economic and social benefits of improved roads, quoting considerable statistical road data and cites examples to show that roads improved by surfacing and reducing the grade and length decrease the cost of hauling, increase the value of farm lands, increase the tourist travel, and improve school and social conditions, and the rural delivery mail service. It discusses the relation of roads to agricultural conditions and states that good roads mean the encouragement of diversified farming, an increase in the area of profitable production, more favorable marketing, and the securing of more uniform distribution of farm products.

In the discussion of hauling cost it is pointed out that the maximum grade of a road tends to limit the load that can pass over the entire road and that steep grades are more detrimental on improved than on unimproved roads, since the grade effect quickly exceeds that of the reduced tractive resistance. Attention is called to the almost total lack of reliable traffic data, and the advisability is suggested of making a traffic census, including total hauling charges, in each locality in order to obtain a ton-mile cost for the various commodities hauled, and therewith compute the amounts of money which may be profitably borrowed for road improvement.

Concrete highways in New York State (*Concrete-Cement Age*, 1 (1912), No. 3, pp. 31-51, figs. 5).—This article includes the principal construction specifications and tabulated data showing the details of concrete road construction, and makes particular reference to a jointless concrete road on Grand Island.

[Specifications for experimental jointless roads] (*Concrete-Cement Age*, 1 (1912), No. 3, pp. 52-54).—Specifications as issued by the Office of Public

Roads of this Department for cement concrete with bituminous surface, oil cement concrete, cement, gravel, crushed limestone, and crushed trap rock for road construction are presented.

**A highway bridge in detail** (*Cement Era*, 10 (1912), No. 10, pp. 30, 31, figs. 2).—Working plans and specifications are given of a novel combination of steel and reinforced concrete in a double span highway structure with reinforced concrete abutments and piers, and reinforced concrete floor supported on steel I-beam girders. The estimate shows 36,491 lbs. of steel and reinforcing and 267½ cubic yards of concrete for the 56 ft. structure.

**Influence of moisture on the expansion and contraction of concrete** (*Engin. Rec.*, 66 (1912), No. 14, pp. 375, 376).—This is an abstract of a paper read by L. W. Page before the Ohio Engineering Society in which he gives the results and conclusions of investigations of the cracking of concrete, especially in road construction soon after completion, due to the inherent contractive qualities of the concrete mass in hardening.

The results show that the contraction and expansion vary with the strength of the mixture, which is a cause for shearing action and separation of the rich top coat from the leaner base mixture in concrete pavements. They further show that if during a period of 6 months the temperature of a concrete mass falls 100° F., each inch of length will contract 0.00055 in.; that if the mass dries, each inch will contract 0.00068 in.; and that there is a further contraction due to the subsequent loss of heat brought about by the chemical action of the cement. In a 100 ft. concrete roadway the contraction might be as much as 1½ in., which brings about an enormous tensile stress causing cracking and breaking up of the pavement.

[**A selection of farm power**], STRECKER (*Maschinen Ztg.*, 10 (1912), No. 16, pp. 185-192, figs. 4).—This is a discussion of the farm power question, making comparisons of the costs of power by electricity, internal combustion engines, and steam. Tables showing cost data are given for all three, with a table of comparative cost data, showing that economy in farm power depends on the use to which it is put, the amount required, the length of time it is to be used, and the local prices per unit of power. When from 8 to 20 horsepower are required for an average of 200 working hours or less per year, electricity is considered the cheapest, but when from 8 to 20 horsepower are required for from 600 to 1,500 working hours or more per year the data indicate that internal combustion power is the cheapest with steam and electricity alternating for second place in cheapness.

**Electricity on the farm**, P. A. BATES (*New York*, 1912, pp. 1661-1679, pls. 12, figs. 3).—This is a paper presented at the twenty-ninth convention of the American Institute of Electrical Engineers in which the author discusses the application of electricity to irrigation and drainage pumping and to farm lighting and machinery driving, describing several installations and pointing out their economic advantages. He discusses public service electric lines and farm cooperative systems, and states that where neither of these is feasible a small private system of lighting may be installed for approximately \$250, and that more power as needed may be generated at reasonable cost. He encourages the use of electricity for lighting, heating, and power because of the great safety from fire.

**Electricity in agriculture**, A. VIETZE (*Arb. Landw. Kammer Prov. Sachsen*, 1911, No. 22, pp. 42, figs. 18).—This pamphlet discusses the farm electric power and light movement with special reference to installation and relative economy of cooperative and central electric farm plants and public service systems, makes comparisons with other sources of power and light, and outlines the

technical and practical details of the use of electricity for farm lighting and for driving the different kinds of farm machinery.

Competitive tests of drills, G. FISCHER (*Arb. Deut. Landw. Gesell.*, 1912, No. 222, pp. 25, pl. 1, figs. 10).—The methods and results of tests of 11 drills having working breadths of from 2 to 4 meters, wheel diameters ranging from 1 to 1½ meters, weights ranging from 400 to 1,200 kg., and prices ranging between 400 and 1,500 marks are described. The drills were tested with oats, peas, beans, wheat, rape seed, corn, and various mixtures of these in single and multiple row work under varying ground conditions, especially noting the influence of ground slope on the working of the machines and the distribution of the grain in the rows.

The results show that with one or two exceptions the drills did fairly good work in distributing the seed, and that the percentage of injured seed was small, although there is still room for improvement. The change in ground surface affected the machines materially, some of them giving very unsatisfactory results on hilly or sloping ground. The principal objections were to the general construction and prices of the machines.

Test of a mowing machine, J. REZEK (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 1 (1912), No. 2, pp. 245-250, pl. 1, figs. 3).—This is an ordinary mowing machine, set on 2 wheels, in which the axle transmits the motion by a ratchet to a set of 4 properly geared cogwheels, one of which is connected to a shaft. The shaft transmits the motion to a wheel and a wooden connecting rod which works the knives back and forth in the sickle. The cogs are thrown in and out of gear by means of a foot lever and the sickle elevation is regulated by a hand lever.

The machine was tested in heavy clover and in green corn in both wet and dry weather and under varying conditions of temperature and ground surface and was found to be a light running, good working, and durable mowing machine. A plan and elevation drawing of the machine accompany this report.

An investigation of the air lift pump, G. J. DAVIS and C. R. WEIDNER (*Bul. Univ. Wis.*, 1911, No. 450, pp. 167, figs. 49).—This bulletin deals with the air lift pump in general, discussing the principles and theory of its operation, as set forth by leading authorities, together with a general description of several types of air lift pumping plants, consisting essentially of an eduction pipe, air compressor, air receiver, air line, foot piece, and tail piece. The disadvantages of the air lift pump are set forth as low efficiency, averaging from 25 to 33 per cent; great depth of submergence necessary for ordinary lifts; limited horizontal pumping capacity; and aeration, causing rusting of parts. The advantages are set forth as large capacity; low maintenance and operating costs; indifference to high temperatures; aeration, causing oxidation of impurities; and reliability. A large amount of data are given resulting from a number of experiments conducted on several different types of this pump showing that the variables which may affect a particular type and size of pump are the percentage of submergence, lift, discharge, volume, and pressure of air.

Farm buildings for landowners, agents, and tenants, C. E. CURTIS (*London*, 1912, pp. VIII+144, pl. 1, figs. 22).—This work deals with the arrangement, design, and construction of farm buildings in a manner simple enough to be intelligible and useful to landowners and their agents and tenants. It contains chapters on farm buildings, farm homesteads, buildings and their arrangement, plans, sections, and elevations, cow stables and covered yards, preservation of rain water, and buildings for small holdings.

A colony poultry house (*Ann. Rpt. Agr. Soc. Ontario*, 12 (1912), pp. 76-78, figs. 3).—A description is given of a portable colony poultry house 12 ft. long and 8 ft. deep set on 4 by 6 in. runners with a frame of 2 by 4 in. scantling,

and with walls, floor, and roof of matched pine flooring. The roof is covered with prepared roofing and the interior fixtures, such as doors, windows, roosts, nests, etc., are arranged to facilitate lighting, ventilating, and cleaning.

**A concrete root cellar.** D. FOLSOM (*Country Gent.*, 77 (1912), No. 39, p. 18, figs. 2).—An outline is given as to the construction of a concrete root cellar, stating that it is essential that the site be well drained and dry under normal conditions to prevent dampness and decay inside. A 1:2:4 mixture is used for the footings, walls, and roof, and a 1:2½:5 mixture for the floor. The roof is reinforced with heavy woven wire fencing, and 2 drain tiles covered with galvanized iron hoods are used as ventilators. A side section of the building is given showing details.

[**Hot water in a greenhouse**], H. L. ALT (*Dom. Engin.*, 60 (1912), No. 12, pp. 292-297, figs. 25).—The details of a hot water heating system satisfying greenhouse requirements, and consisting of 2-in. wrought iron pipe coils in sufficient quantity to maintain an average temperature of 60° F. in a total heating space covering some 6,000 sq. ft., are presented.

## RURAL ECONOMICS.

**Work accidents and the farm hand.** D. J. LESCHIER (*Survey*, 27 (1911), No. 1, pp. 946-951, figs. 4).—This article discusses and illustrates the economic significance of farm accidents. It shows that much of the machinery used on the farm is more dangerous than that used in most factories, since the public has not known enough about the number, causes, and consequence of accidents on farms to realize that farm workers need legal protection against unguarded machinery as badly as do factory workers.

A table itemizing the 135 agricultural accidents in Minnesota for a period of 20 months is given. Of these accidents 16 were fatal, and 9 involved the loss of an arm, 10 of a hand, 42 of one or more fingers, and 1 each of a foot, a leg, or both eyes. There were also 16 breaks and fractures, 16 serious and 7 severe crushings, and 13 serious and 9 severe lacerations.

**Possibilities of American farms.**—A comparison with Germany, E. MERRITT (*Tribune Farmer* [N. Y.], 11 (1912), No. 570, p. 2).—The author considers it inexpedient to attempt to reach Germany's standard of production in this country at present, and discusses the differences in conditions. "As soon as the increase in population creates a demand, our farmers will increase their production to meet it."

**The high cost of farming.** B. F. YOAKUM (*World's Work*, 24 (1912), No. 5, pp. 519-533, figs. 18).—This is the first of a series of articles discussing the causes of an alleged decrease in the purchasing power of the dollar in America from 100 cts. to 70 cts. during the last 15 years as compared with a decrease in England from 100 cts. to 78 cts., and a still smaller contraction in Germany. The causes assigned are the excessive burden of interest charges on farm loans because of inadequate money-lending facilities, the excessive cost of selling and delivering farm products to the consumer, the excessive cost of cartage from the farm to the railroad because of poor roads, and the need for more and better railroads.

The author discusses each item in detail, showing the cost of these deficiencies, the steps taken in other countries to eliminate them, and the steps needed in America to that end. As an illustration of one difficulty under which the American farmer does business, it is stated that whereas the United States Government can borrow money for \$20 per annum per \$1,000, and New York call loans command \$24.60, commercial paper in the United States \$41.10, French farms \$43, German farms \$44, the best public utilities or New York

mortgages \$50, average American industries \$65, and Arab farms in Egypt \$80, the rate paid on the average American farm is \$85.

**Cheap money for farmers.** J. W. WARD (*Grain Growers' Guide*, 4 (1912), Nos. 38, pp. 7, 21, 22, 30; 39, pp. 8, 13, 14).—This is a series of articles discussing and outlining a system of government loans for the farmers of western Canada based on the experience of Australia, New Zealand, and Germany. It is proposed that the provincial governments, upon the credit of the Provinces, borrow on the market at 4 per cent, allow 1 per cent for the cost of administration, and loan the money to farmers at 5 per cent, the initial expenses in the way of inspecting the property which is to be security for the loan, the drawing of mortgages, etc., to be borne by the borrower. It is suggested that the loans be limited to about 50 per cent of the value of the property on which they are to be secured, except that, in the case of homesteaders who have not earned their titles, provisions might be made to advance them a certain proportion of the value of the improvements which they have made.

**Agricultural cooperation in Switzerland** (*Tribune Farmer* [N. Y.], 11 (1912), No. 570, p. 5).—This is stated to be one of a series of reports from American diplomats abroad regarding farmers' cooperative systems of various countries.

It is shown that one of the principal purposes of the Swiss Farmers' Association, which is represented in the Swiss National Council, is to regulate to a large extent the prices of milk and other agricultural products in the interest of the farmer. Similar associations with the same principles and purposes have also been established in the various cantons (States) and are members of the Swiss Farmers' Association. Besides these there are a number of local cooperative societies which have for their purpose the purchasing of seed, fertilizers, etc.

The federal government contributes annually 25,000 francs to the expenses of the central bureau maintained by the Swiss Farmers' Association. In the various cantons provisions are also made to facilitate loans to farmers through government mortgage banks, the chief advantage of which is that the farmer does not have to repay the loan in a single payment and he is practically relieved from the danger of foreclosure of his mortgage. Financial aid may also be rendered by municipal, cantonal, and federal authorities to undertakings which have for their purpose the improvement of the soil in the way of irrigation, drainage, road making, fencing, etc.

**Institutions for agricultural credit** (*An. Statis. Românici*, 1912, pp. 176-245).—Statistical tables are here presented giving detailed accounts of the condition and growth of agricultural credit societies; the status and extent of the loans; and the establishment, work, and progress of rural banks; together with other data relating to the many phases of agricultural credit in Roumania.

**Cooperative agricultural distribution and production** (*Bd. Trade [Gt. Brit.], Abs. Labor Statis. United Kingdom*, 15 (1912), pp. 248-253).—Tables are given presenting a general summary as to the number and total sales of cooperative societies in the United Kingdom engaged in agricultural distribution and production in each of the years 1896-1910, distinguishing the classes of societies. Other tables show capital, amount of land, sales, etc., of the cooperative small holdings and allotments societies in each of the years 1908-1910, together with the number of cooperative credit associations, members, capital, amount of loans granted, and other particulars for the years 1901-1910.

**Small holdings.** E. J. CHENEY (*Bd. Agr. and Fisheries [London], Ann. Rpt. Proc. Small Hold. and Allot. Act [etc.]*, 1911, pp. 99).—The data here reported have been previously noted (E. S. R., 27, p. 592).

**A handbook of Virginia**, G. W. KGINER (*Richmond, Va.: Dept. Agr. and Immigr., 1911, 4. ed., pp. 272, pl. 1, figs. 87*).—This publication shows the agricultural resources, as well as the agricultural and industrial development, of Virginia during the last decade. It is noted that the value of farm crops produced in the State increased from \$129,000,000 in 1900 on 4,000,000 acres to \$236,000,000 in 1910 on 3,300,000 acres.

[**Agricultural products and resources of Mexico**] (*In Mexico: A General Sketch. Washington, D. C.: Pan American Union, 1911, pp. 80-158, pl. 1, figs. 29*).—This publication presents along with other data a compilation as to the extent and character of the agricultural products and resources, timber and timber products, stock raising, mining, other industries, etc., of Mexico.

**Agricultural progress in Trinidad and Tobago**, CARMODY (*Dept. Agr. Trinidad Bul., 11 (1912), No. 70, pp. 15-23*).—An address delivered at the West Indian Agricultural Conference held at Trinidad January 23-30, 1912, in which the author points out the many directions in which progress has been made in the colony. Statistics are given comparing the principal agricultural exports for the years 1895-1900, 1903-4, and 1910. The principal crops, named in the order of their importance, are cacao, sugar, coconut, rice, and coffee. The value of exported cacao amounted in 1910 to £1,230,097.

**Agricultural statistics, 1911**, R. H. REW (*Ed. Agr. and Fisheries [London], Agr. Statis., 46 (1911), No. 1, pp. 97, fig. 1: abs. in Jour. Roy. Agr. Soc. England, 72 (1911), pp. 409-418*).—A report presenting notes and statistics as to the acreage and live stock returns of Great Britain, with summaries for the United Kingdom.

The total land area of Great Britain is reported for 1911 as 56,214,419 acres, of which 32,094,658 acres are returned as cultivated area, a decrease of 51,272 acres as compared with 1910. During the last 10 years the reduction of the cultivated area has amounted to 323,000 acres.

The agricultural holdings containing from 1 to 5 acres numbered 108,552 in 1910, and 110,596 in 1911; those containing from 5 to 50 acres numbered 232,585 in 1910, and 234,040 in 1911; the farms having from 50 to 300 acres numbered 151,102 and 151,197 in 1910 and in 1911, respectively; and the number containing over 300 acres is reported at 17,426 in 1911, as compared with 17,569 in 1910. Of the total number of holdings 60,217, or 1.73 per cent, are operated by the holders, and 43,239 of these are holdings from 1 to 50 acres.

Tables are given, showing the acreage under crops and grass and the number of live stock in each division of Great Britain in 1911 and 1910; number of holdings farmed; acreage under orchards; and the different kinds of small fruits, other crops, etc., for each county in 1911.

**Agricultural statistics (Statis. Jahrb. Schweiz, 20 (1911), pp. 40-57)**.—An official report giving agricultural statistics of Switzerland by cantons, showing the area in cultivation, the average and total yields, value, etc., of the leading crops, the production, value, etc., of dairy products, and other agricultural data for varying periods.

**Foreign crops, July, 1912**, C. M. DAUGHERTY (*U. S. Dept. Agr., Bur. Statis. Circ. 39, pp. 15*).—This circular presents notes and statistics as gathered from reports of various foreign countries regarding crop conditions, area, production and estimated yields of foreign crops, 1911-12, with comparisons; together with statistics as to imports of wheat and wheat flour into Belgium, 1906-1911; and imports of cotton into European and Asiatic Russia, 1906-1910.

**Crop Reporter (U. S. Dept. Agr., Bur. Statis. Crop Reporter, 14 (1912), No. 8, pp. 57-64, fig. 1)**.—Notes and other data showing crop conditions August 1, 1912, with comparisons are here presented; also receipts at and exports of durum wheat from the principal United States ports 1908-1912; farm value of

important products by States and on various dates; farm marketing and prices of wheat by months; value of the foreign trade of the United States, 1903-1912; hay, temperature, and precipitation statistics; average world production of important agricultural products; production of sugar and sugar cane in the Territory of Hawaii, 1910-11; and range of prices of agricultural products at important markets.

**Crop Reporter** (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 14* (1912), No. 9, pp. 65-72, fig. 1).—A report showing crop conditions September 1, 1912, with comparisons, is given; likewise data as to the monthly receipts and stocks of eggs and poultry in the United States; farm value of important products on dates indicated; average condition of all crops, by States; average condition of specified crops, United States; temperature and precipitation statistics; farm value of important crops; imports of farm and forest products; monthly movements of grain from farms; and the range of prices of agricultural products at important markets.

The total cotton ginned in the various States up to September 1 was 729,926 bales for 1912, as compared with 771,297 for 1911, 353,011 for 1910, and 388,242 for 1909.

### AGRICULTURAL EDUCATION.

**The university ideal**, A. M. SOULE (*Athens, Ga., 1912, pp. 20*).—This is a discussion of the origin, rise, and influence of the American university system, considering such functions of a university as the maintenance of a graduate school, leadership in public affairs, and extension work.

**Educational culture for the people of Manitoba**, J. W. ROBERTSON ([*Winnipeg: Univ. of Manitoba*], 1912, pp. 8).—This address, given at the convocation of the University of Manitoba, makes a strong plea for such further reorganization and reconstruction of "courses" and "time tables" in schools, colleges, and universities as will insure a full measure of an educational culture as suitable for the fundamental vocations or occupations as the formal education of the recent past has been for the learned professions.

**Report of agricultural extension department**, E. S. RICHARDSON (*Univ. Bul. La. State Univ., n. ser., 3* (1912), No. 6, pt. 1, pp. 16).—A report of the work accomplished by the department since its organization in 1909.

**Something of the district agricultural schools** (*Farmers' Union Sun, 14* (1912), No. 26, pp. 3, 4).—A popular description of the work at the Statesboro Agricultural School of Georgia, which last season had an enrollment of 253 pupils, 50 of whom were girls. The boys do all the farm work, each student being required to put in 9 hours a week on the farm and 4 in the shop, and being paid by the hour for all additional time. The same principle is applied in the girls' department.

**Report of agriculture in the high schools of Michigan**, W. H. FRENCH (*Mich. Agr. Col., Dept. Agr. Ed. Bul. 8, 1912, pp. 23, figs. 15*).—This report gives the plans and purposes of the work and what has been accomplished up to the present time. A statistical table shows the enrollment in agricultural classes, expenses for instruction, and the character of the extension work.

**High schools that train for farming**, C. W. WARBURTON (*Country Gent., 77* (1912), No. 31, pp. 7, 24, fig. 1).—This is an account of how Minnesota schools are adapted to the needs of country pupils.

**Country schools for city boys**, W. S. MYERS (*U. S. Bur. Ed. Bul., 1912, No. 9, pp. 22, pls. 5*).—A few of the results thus far obtained from the establishment of a country school for city boys at Baltimore, Md., and other places are given. The movement has been supported entirely by private means.

**Preparation of teachers for rural work.** A. C. MONAHAN (*Winthrop Norm. and Indus. Col. S. C. Bul.*, 5 (1911), No. 1, pp. 32-40).—The author maintains that, in the future, economy and efficiency will force the number of one-room district schools to decrease constantly and the number of consolidated or centralized schools, to which the pupils are transported at public expense, to increase greatly; that agriculture, home economics, prevention of diseases, sanitation, and good citizenship should be included in the curriculum; and that the teacher become a permanent part of the community. Although the teacher need not be an expert farmer, housekeeper, doctor, or nurse, she should be well enough informed in these subjects to teach their elements and to aid in the direction and arrangement of more complete instruction for adults.

**The rural school.** F. S. COOLEY (*Bul. Mont. State Col. Agr.*, 9 (1911), No. 2, pp. 20).—This bulletin contains, among other things, suggestions for rural teachers and others who are interested in developing plans to assist the schools in the discharge of their full function as an agency for country betterment.

**The organization of correspondence courses in agriculture.** J. HAMILTON (*Proc. Assoc. Amer. Agr. Cols. and Expt. Stas.*, 25 (1911), pp. 186-193).—The author outlines a plan of extension teaching by the correspondence method, in which he suggests the formation of classes of not more than 15 persons to meet daily from 8 a. m. to 4.30 p. m. for a limited period, under the direction of a leader. The leader would in most cases be a layman residing in the neighborhood, and should be appointed by the extension department of the agricultural college. His main business would be to see that the students did the required work, to conduct quizzes, assist students in reference work, oversee the practicum, have charge of apparatus and materials for laboratory work, keep records, and make reports. The course of study should be printed in detail and should be upon a single topic for each class organized. Suggestions are given for the various details of conducting classes in this way, for summer schools for training class leaders, and for the organization of the necessary office force.

**Opportunities in the government service.** D. S. BURCH (*Wis. Country Mag.*, 6 (1912), No. 4, pp. 11-14).—In this discussion, the term "government service" refers to work in the U. S. Department of Agriculture.

**State aid to agriculture in Ireland.** H. PLUNKETT (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 37-61).—This is a detailed account of the administration of state aid for agricultural instruction in Ireland, dealing chiefly with the policy and work of the Department of Agriculture and Technical Instruction for Ireland.

**Statistics of education in the Kingdom of Wurtemberg for 1911** (*Statist. Unterr. u. Erziehungsw. Kgr. Württemb.*, 1911, pp. 64).—Information is given for 1911 similar to that for 1910 previously noted (E. S. R., 27, p. 695).

**School agriculture.** M. N. WOOD (*New York and London*, 1912, pp. XV+339, pls. 14, figs. 180).—This book is intended for classes in rural and graded schools, and includes most of the principles of general agriculture. Experiments and a suggestive list of reference books follow each chapter. Considerable attention is given to illustrations developing the different topics.

**A tentative course of study in the subject of agriculture for the elementary schools of the State of Ohio for the year 1911-12.** F. W. MILLER ET AL. (*Columbus, Ohio: [Dept. Ed.] 1911*, pp. 11).

**Lessons from forest and orchard.** A. W. NOLAN (*Agr. Col. Ext. Univ. Ill.* [Circ.], 1912, July, pp. 35, figs. 16).—Six lessons in forestry and 7 in orchard management are presented, also practical exercises to be correlated with the school work in nature-study and elementary agriculture.

**The renewal of the neglected orchard.** C. S. WILSON (*Cornell Reading-Courses, Fruit Growing Ser.*, 1912, No. 1, pp. 173-180, figs. 5).—Directions of

general application are presented. A supplement contains 11 suggestive questions for the teacher in orchard management.

**Elementary entomology.** E. D. SANDERSON and C. F. JACKSON (*New York, Chicago and London, 1912, pp. V+372, figs. 496*).—This work has been prepared as a text-book for beginners in entomology. Parts 1 (pp. 5-66) and 2 (pp. 67-274), by the senior author, deal with the structure and growth of insects and with the classes of insects. Part 3 (pp. 275-358), by the junior author, is devoted to laboratory exercises.

**Notes in agricultural arithmetic.** C. A. WHEELER (*Storrs, Conn., 1912, pp. 77, figs. 104*).—In the development of this subject, the author has made use of grades to give practice in percentage; of scales and free-hand lettering forms to encourage neatness in the students' work; and of isometric projection. The contents include chapters on foods, fertilizers, and painting.

**Cement silo construction.** G. S. HINE and G. C. WHEELER (*Agr. Ed. [Kans. Agr. Col.], 4 (1912), No. 6, pp. 79, figs. 29*).—This publication gives data on building solid-wall and metal-lath silos.

**Civic improvement in village and country.** F. A. WAUGH (*Facts for Farmers [Mass. Agr. Col.], 2 (1912), No. 12, pp. 4*).—A suggestive outline of work for those interested in community betterment.

**Public schools and community life.** E. L. HOLTON (*Vocational Ed., 1 (1912), No. 5, pp. 351-354*).—The author points out the necessity for the redirection of schools toward the home, farm, shop, and higher levels of community life, not theoretically but practically, and cites what is being done in Kansas through improvement clubs in several hundred rural neighborhoods, the teaching of agriculture in more than 7,000 rural schools and about 450 city and village schools, and of home economics in about 700 rural schools and 200 village and city schools, one-day agricultural fairs in rural and village schools, and short winter courses for farmers and farmers' wives in several county high schools and one or two city schools. The program of a rural school improvement meeting is given, as is also an outline of a 2-year course followed in a high school in Wisconsin.

**The text-book of agricultural education and rural life: Boys' and girls' agricultural clubs.** T. W. HORTON (*Columbus: Ohio Assoc. Adv. Agr. Ed. [1912], pp. 20, figs. 6*).—The author states that boys' and girls' agricultural and domestic science clubs offer a most useful means of solving the problem of giving boys and girls an opportunity to put into actual practice in the soil or in the house the lessons learned in the school, and also giving useful vacation work to connect the school and home life. An account is given of a club organized in March, 1911, in Scioto Township, Pike County, Ohio.

**The school-home garden.** E. C. BISHOP (*Nature-Study Rev., 8 (1912), No. 5, pp. 169-172*).—According to the author, in schools where vacation work is not practicable, the mission of the school garden should be (1) as an experimental plot for the study of germination of seeds and root and stem development so far as is possible when school is in session; (2) for the growing of vines and shrubs, which may help to cover or shield the view of outbuildings and form a part of the schoolground landscape work; (3) for the growing of such other plants as may be given a start in the spring, and by mulching or other pre-arranged care during the summer, blossom or bear results at the fall opening of school; and (4) as an experimental or demonstration garden on a small scale, to create an interest that will impel pupils to plant gardens of their own at home.

**West Virginia Arbor and Bird Day manual** (*Charleston, W. Va.: Dept. of Schools, 1912, pp. 78, pls. 16, figs. 15*).—This contains suggestions and material for the observance of the day.

**Arbor Day in Porto Rico** (*San Juan, P. R.: Dept. Ed., 1911, pp. 47*).—This pamphlet, published in English and in Spanish, contains a program and other material for the celebration in the public schools of Porto Rico of Arbor Day, which occurs on the Friday following the last Thursday in November.

**Farmers' institutes in Pennsylvania**, compiled by A. L. MARTIN (*Penn. Dept. Agr. Bul. 217, 1911, pp. 82*).—This bulletin contains information for institute managers and program committees on institute work in Pennsylvania, and other data.

### MISCELLANEOUS.

**Twenty-second Annual Report of Mississippi Station, 1909** (*Mississippi Sta. Rpt. 1909, pp. 14*).—This contains the organization list, a financial statement for the federal and sales funds for the fiscal year ended June 30, 1909, and for the substations for the period from May 16, 1908, to April 23, 1909, and a report by the director on the work of the station during the year.

**Twenty-third Annual Report of Mississippi Station, 1910** (*Mississippi Sta. Rpt. 1910, pp. 12*).—Data corresponding to the above are given for the period ended June 30, 1910.

**Annual Report of Porto Rico Station, 1911** (*Porto Rico Sta. Rpt. 1911, pp. 44, pls. 4*).—This contains the organization list, a summary by the Special Agent in Charge of the investigations conducted at the station during the year, and separate reports by the chemist, horticulturist, assistant horticulturist, entomologist, pathologist, and animal husbandman. The experimental work reported is for the most part abstracted elsewhere in this issue.

**Partial bibliography and index of the publications of the college of agriculture and the agricultural experiment station** (*Missouri Sta. Bul. 105, pp. 19*).—This comprises a bibliographical list and index to Farm Bulletins 1 to 35 of the college of agriculture, and the following publications of the station: Bulletins 1 to 82, Circulars 1 to 45, and the Reports of the Director from 1888 to 1903.

**Experiment Station Work, LXX** (*U. S. Dept. Agr., Farmers' Bul. 504, pp. 24, figs. 3*).—This number contains articles on the following subjects: Improvement of sandy soils—growth of forage crops, utilization of roughage, fattening lambs on alfalfa and corn, box for feeding alfalfa hay to swine, cooperative herd testing, cooperative cattle breeding, losses due to low-grade cream, lessening danger from poisoning by arsenical dips, and care of farm machinery.

## NOTES.

---

**Connecticut Stations.**—Director E. H. Jenkins, of the State Station at New Haven, has been appointed director of the Storrs Station. The board of managers, the funds, and the work of both stations will be separate as in the past, but a single director will administer both stations.

**Delaware College.**—A summer school for teachers, giving instruction in agriculture and home economics, is to be held in 1913, the State Board of Education having recently required the teaching of these subjects in the public schools beginning next fall.

**Kansas College.**—A secondary school of agriculture, mechanic arts, and home economics is to be established next fall to articulate with the eighth grade of the public schools. A three-year course will be offered, with a fourth year for those desiring to enter the college. The present subfreshman course is to be abolished and the entrance requirements raised to 15 units.

**Massachusetts Station.**—H. D. Goodale, a specialist in zoology and since 1911 employed by the Carnegie Institution of Washington in its department of experimental evolution, has been appointed research biologist in the department of poultry husbandry. He will begin his duties February 1, 1913.

**Minnesota University and Station.**—Dr. E. M. Freeman has been appointed assistant dean. G. W. Paterson has succeeded J. B. Lamson as assistant in rural school work. Other appointments include J. H. Allison as professor of forestry, F. A. Cornica instructor in the school of agriculture, Florence Secor instructor in domestic art, and Charles L. Lewis assistant in drainage investigations. Stephen Anthony has been given leave of absence as chemist in animal nutrition.

**Porto Rico Sugar Producers' Station.**—A meeting was recently held at Fajardo, on the eastern side of the island, for the discussion of irrigation problems. This has been a very dry year and even plantations on the north and east coasts, which usually have sufficient rainfall for sugar cane, have suffered to such an extent that the establishment of irrigation works is being seriously considered. An irrigation engineer of the Department of the Interior was present at the meeting and discussed the engineering features of the problem, and much interest in the subject has been aroused.

**Tennessee University and Station.**—The State Veterinary Medical Association met at the university November 20 and 21 for the first time. The program included a practical demonstration of the vaccination of hogs against cholera. A resolution was passed favoring an appropriation by the State for the establishment of a hog cholera serum plant in connection with the university and station.

A corn exhibit was held November 23, on the station farm, by the boys' corn clubs of eastern Tennessee. There are clubs in 16 of the 34 counties, and the membership numbers about 600. Prizes are awarded valued at \$500, besides local prizes valued at approximately \$3,000 additional.

## INDEX OF SUBJECTS.

NOTE.—The abbreviations "Ala. College," "Conn. State," "Mass.," etc., after entries refer to the publications of the respective experiment stations; "Alaska," "Hawaii," and "P.R." to those of the experiment stations in Alaska, Hawaii, and Porto Rico; "Can." to those of the experiment stations in Canada and "U.S.D.A." to those of this Department.

Abacú, binder twine from, U.S.D.A. ....	534	Acids, organic, as affected by fungi. ....	526
Abattoirs. (See Slaughterhouses.)		effect on carbon assimilation	
<i>Ablerus cliocampe</i> , notes U.S.D.A. ....	556	of plants. ....	525
n. sp., notes, U.S.D.A. ....	556	respiration of seeds..	729
Abortion—		wheat bread. ....	462
contagious, diagnosis. ....	682	volatile, formation after fermentation.	223
Wis. ....	582	in honey. ....	112
notes. ....	77	Acorns, analyses. ....	371, 872
Mich. ....	181	composition and digestibility. ....	669
infectious, diagnosis, Ky. ....	581	drying. ....	669
etiology. ....	576	Aceridinae, notes. ....	858
in cattle. ....	77, 287, 478, 885	Aceridoidea, South American, notes. ....	55
mares. ....	77	Actinomycosis of the rectum in horses. ....	86
investigations. ....	581	<i>Actinonema roseæ</i> , treatment, Can. ....	747
Ky. ....	580	Adobe as a building material, U.S.D.A. ....	599
Absinth, notes, U.S.D.A. ....	665	<i>Egeria webberi</i> , notes, Fla. ....	350
Absorption in solutions, discussion. ....	215	U.S.D.A. ....	860
<i>Acacia arabica</i> , beetles affecting. ....	863	<i>Ægilops orata</i> , chromosome numbers in. ....	636
spp., analyses and digestibility. ....	871	<i>Enoplogymorpha phytanomi</i> , notes, U.S.D.A. ....	561
Acarina, parasitism in. ....	866	Aeration of soils. ....	419
<i>Accipiter cooperi</i> , notes, U.S.D.A. ....	355	<i>Æsiotes leucurus</i> , notes. ....	60
<i>Acer macrophyllum</i> , notes, U.S.D.A. ....	846	Afforestation. (See Forestation.)	
<i>Acerates viridiflora</i> , leaf variation in, N.J. ....	741	<i>Agallia sanguinolenta</i> , notes, U.S.D.A. ....	858
Acetanilid, determination in headache tablets. ....	499	<i>Agaricus mucidus</i> , notes. ....	51
Acetic acid, effect on bread fermentation. ....	268	<i>Agave</i> spp., binder twine from, U.S.D.A. ....	534
occurrence in silage, Conn. Storrs. ....	205	Agaves, studies. ....	33
Acetyl group, occurrence in lignin. ....	310	<i>Agelastica</i> sp., notes. ....	453
Acetylene gas, effect on plants. ....	826	Agglutination, acid, of bacteria. ....	334
<i>Achoreutes armatum</i> , notes, U.S.D.A. ....	658	reactions in hog cholera. ....	289, 384
Acid excretion of roots. ....	514	Agricere of soils, notes. ....	621
phosphate. (See Superphosphate.)		Agricultural—	
reaction on milk. ....	810	arithmetic, notes. ....	898
Acidity, determination in milk. ....	113	associations in Netherlands. ....	798
Acids, amino, behavior in soils. ....	500	northern Europe. ....	590
effect on <i>Penicillium glaucum</i> . ....	526	banks in Pennsylvania. ....	389
hydrolytic action. ....	802	benevolent institution in England. ....	795
occurrence in grape leaves. ....	731	Chemical Institute at Zurich, report. ....	413
place of retention in the body. ....	169	chemistry. (See Chemistry.)	
precipitating agents for. ....	713	clubs for boys and girls. ....	898
determination in cane juice. ....	814	junior, in Oklahoma. ....	395
effect on activity of sucrase. ....	803	colleges—	
<i>Aspergillus niger</i> . ....	848	and experiment stations, relationship. ....	490
bread fermentation. ....	268	effect on higher education. ....	605
fatty, determination. ....	497	in United States, statistics. ....	797
occurrence in milk. ....	113	rôle in rural life. ....	595
preparation for lüter test. ....	497	unprepared teachers in. ....	490
monoamino, detection in presence of polypeptides. ....	410	(See also Alabama, Arizona, etc.)	
nonvolatile, of butter, refraction. ....	312	colonization in Ontario. ....	794
		committees of bankers' associations. ....	399
